In this article, we investigate the logical structure of memory models of theoretical and practical interest. Our main interest is in "the logic behind a fixed memory model", rather than in "a model of any kind behind a given logical system". As an effective language for reasoning about such memory models, we use the formalism of separation logic. Our main result is that for any concrete choice of heap-like memory model, validity in that model is *undecidable* even for purely propositional formulas in this language.

The main novelty of our approach to the problem is that we focus on validity in specific, concrete memory models, as opposed to validity in general classes of models.

Besides its intrinsic technical interest, this result also provides new insights into the nature of their decidable fragments. In particular, we show that, in order to obtain such decidable fragments, either the formula language must be severely restricted or the valuations of propositional variables must be constrained.

In addition, we show that a number of propositional systems that approximate separation logic are undecidable as well. In particular, this resolves the open problems of decidability for Boolean BI and Classical BI.

Moreover, we provide one of the simplest undecidable propositional systems currently known in the literature, called "Minimal Boolean BI", by combining the purely positive implication-conjunction fragment of Boolean logic with the laws of multiplicative *-conjunction, its unit and its adjoint implication, originally provided by intuitionistic multiplicative linear logic. Each of these two components is individually decidable: the implication-conjunction fragment of Boolean logic is co-NP-complete, and intuitionistic multiplicative linear logic is NP-complete.

All of our undecidability results are obtained by means of a direct encoding of Minsky machines.

1. INTRODUCTION

In this article, we investigate the logical structure of natural memory models of theoretical and practical interest, our main focus being "the logic behind a fixed memory model" rather than "a model of any kind behind a given logical system". We use *separation logic* to provide a formula language for such memory models, justified by the fact that, among other things, within this language we can explicitly express basic operations over memories, such as the conflict-free union of disjoint pieces of memory. Furthermore, in the last decade separation logic has become well-established as

a practically effective formalism for specifying the properties of such memory models and reasoning about programs that manipulate memory, in the form of pointers, heaps, stacks, etc. [Reynolds 2002; Ishtiaq and O'Hearn 2001; Calcagno et al. 2007]. Automated shape analysis tools based upon separation logic are capable of verifying properties of large industrial programs [Yang et al. 2008; Calcagno et al. 2011], and have been adapted to a variety of paradigms such as object-oriented programming [Parkinson and Bierman 2008; Distefano and Parkinson 2008; Gardner et al. 2012] and concurrent programming [Dodds et al. 2009; Gotsman et al. 2009].

Separation logic is usually based on a memory-oriented mathematical model of *heap* partitioning. In addition to the standard "additive" Boolean connectives, which are read in the usual way, separation logic features certain "multiplicative" connectives which are interpreted as operations in this model. The most important of these is the so-called separating conjunction *, which generally denotes a partial operator for composing heaps whose domains are disjoint: $A_1 * A_2$ denotes the set of heaps which can be split into two disjoint heaps satisfying, respectively, A_1 and A_2 . The separating conjunction * comes along with its *unit* I, which denotes the empty heap, and its *adjoint implication* $A_1 \rightarrow A_2$, denoting those heaps whose extension with any heap satisfying A_1 , satisfies A_2 . Depending on the application, first-order quantifiers and inductively defined predicates may also be included in the logic.

One of our main contributions in this article is that, irrespective of the choice of underlying memory model, separation logic is undecidable, even at the purely propositional level.

The novelty of our approach to the problem is that we focus on concrete memory models of practical interest, and prove that, whichever concrete heap-like memory model we choose, the validity of propositional separation logic formulas in that model is undecidable. The models we consider—which include the most common memory models used in practice—are listed in Section 2.

As an immediate corollary of this strict result about validity in fixed models, we also obtain undecidability of validity in various classes of such models, and undecidability of provability in several closely related propositional systems.

1.1. Validity in Fixed Models vs. Validity in Classes of Models

Validity in a fixed model of practical interest is a much more subtle problem than validity in general classes of models.

As usual, to demonstrate that a validity problem in a classes of models is undecidable, we aim to exhibit a reduction from the halting problem for a suitable class of machines. In our case, these are nondeterministic, 2-counter Minsky machines. Thus, given a formal system, we can construct a provable formula $\mathcal{F}_{M,C}$ in its language which is intended to represent the termination of the Minsky machine M from the configuration C. By soundness of the system, provability of $\mathcal{F}_{M,C}$ implies its validity in some class of models.

In order to prove the faithfulness of our encoding, we have to show the converse direction that if $\mathcal{F}_{M,C}$ is valid in this class of models then M terminates from C. Now, traditionally, to show that a formula \mathcal{F} has the desired property Q given that \mathcal{F} is valid in a *class* of models, one constructs *some* "canonical" model \mathcal{M} in this class such that validity of \mathcal{F} in this specially designed model \mathcal{M} implies Q.

However, when we consider the problem of validity in a concrete model \mathcal{M}_0 specified in advance, we have no such freedom. Instead, we have to show Q given only that \mathcal{F} is valid in this fixed concrete model \mathcal{M}_0 . The difficulty of this task is that there is no ad hoc connection between the given model \mathcal{M}_0 (of practical interest) and the artificially designed "canonical" model \mathcal{M} one would normally seek to create.

Since existing decidable fragments of separation logic are based on concrete models, an additional advantage of our approach is that our undecidability results for these models illuminate the restrictions on these fragments. In particular, it transpires that undecidability is closely connected to the tradeoff between finite and infinite valuations of the atomic propositions (cf. Section 10).

Seen as a proof system, separation logic invokes a first-order extension of the propositional *bunched logic* Boolean BI [Ishtiaq and O'Hearn 2001]. Bunched logics, originating in the "logic of bunched implications" BI [O'Hearn and Pym 1999], can be conceived of as substructural logics that combine a standard propositional logic with various "multiplicative" connectives originally provided by linear logic (cf. Pym [2002] and Brotherston [2012]). Their practical significance for computer science stems from their Kripke-style truth interpretation in which the "worlds" of the Kripke models are understood as *resources* [Ishtiaq and O'Hearn 2001; Pym et al. 2004; Brotherston and Calcagno 2010].

In proving our main undecidability results, we also establish the undecidability of provability in several propositional systems based on bunched logic. In particular, these include the bunched logics Boolean BI [Ishtiaq and O'Hearn 2001] and Classical BI [Brotherston and Calcagno 2010].

1.2. Summary of the Structure of the Article

The remainder of this article is structured as follows:

First, in Section 2, we list a series of natural memory models of theoretical and/or practical interest in various subfields of computer science and mathematics. Then, in Section 3, we give the formula language and semantics of propositional separation logic, which is suitable for expressing properties of these memory models, and, in Section 4, we present a number of propositional logical systems that arise naturally in developing towards an axiomatisation of separation logic and memory models.

An overview of our undecidability results and the proof methodology used to establish them is then given in Section 5. The proofs themselves occupy Sections 6–9, which are mainly technical.

In Section 6, we give a minimal version of Boolean BI, called Minimal BBI, in which negation and falsum are disallowed; this system looks "as simple as possible", but is nonetheless proved to be undecidable.

In Section 7, we encode two-counter Minsky machines as sequents of Minimal BBI so that whenever the machine M terminates from configuration C, the corresponding sequent $\mathcal{F}_{M,C}$ is provable in Minimal BBI. The proof of this fact is given in Section 8. By soundness, the sequent $\mathcal{F}_{M,C}$ is then valid in any memory model chosen from Section 2.

Then, in Section 9, we show that whenever $\mathcal{F}_{M,C}$ is valid in one of these concrete models listed in Section 2, the machine M must terminate from configuration C. The proof of this fact is divided into two stages. First, we consider an intermediate partial *RAM-domain* model (cf. Section 2.5), a degenerate heap model in which the information content of the memory cells is removed, leaving only their "address space". Then, we establish the necessary connection between validity in the RAM-domain model and validity in any of the actual heap-like memory models.

It follows from the main results outlined previously that "any property between provability in Minimal BBI and validity in a heap-like model is undecidable" (see Figure 1, Section 5).

In Section 10, we examine the limitations on decidable fragments of memory models imposed by our undecidability results. Of course, one option for obtaining such decidable fragments is to constrain the formula language so that sequents of the form $\mathcal{F}_{M,C}$ cannot be expressed, which can be done, for example, by excluding the multiplicative implication –*, as happens in Berdine et al. [2004] and in most of the verification tools employing separation logic (cf. Yang et al. [2008], Distefano and Parkinson [2008], and Calcagno et al. [2011]).

Oddly enough, however, it also happens that validity under all finite valuations for atomic propositions in a heap-like model does not imply general validity in that model. Consequently, at least in some models, decidable fragments of memory models can be obtained by restricting valuations to be finite (cf. Calcagno et al. [2001]).

In Section 11, we consider "dualising" separation models and related propositional systems based on Classical BI [Brotherston and Calcagno 2010]. Models of Classical BI differ from the models in Section 2 in that every element is required to have a unique dual; thus, for example, every Abelian group is a model of Classical BI (in which the dual of element is its group inverse), as are bit arrays (where the dual of an array is given by inverting each of its bits). Classical BI is a nonconservative extension of Boolean BI, and thus validity in its models behaves quite differently. Nevertheless, we show that our encoding of Minsky machines also yields undecidability of systems based on Classical BI, and undecidability of validity in associated classes of models.

1.3. Related Work

The present article is an extended and revised version of a conference paper which appeared at LICS 2010 [Brotherston and Kanovich 2010].

Here, we report on the main developments in the literature related to our undecidability results, both before and since their original publication in Brotherston and Kanovich [2010].

- —The decidability of the bunched logic Boolean BI (BBI, for short) was widely considered an open problem for quite a long time (see, e.g., Galmiche and Larchey-Wendling [2006]). As mentioned previously, undecidability of Boolean BI is a consequence of our general undecidability results for fixed heap-like memory models. However, immediately prior to publication of Brotherston and Kanovich [2010], we discovered that undecidability of BBI can in fact be deduced from the undecidability of equational theories over commutative residual monoids claimed in Kurucz et al. [1995]. More precisely, Kurucz et al. [1995] contains the claim that the equational theory of "CRM" (standing for "Commutative Residuated Monoids"), a certain class of algebras defined in Jipsen's Ph.D. dissertation [Jipsen 1992], is undecidable. Following the reference to Jipsen [1992], one can see that the equational theory of CRM corresponds exactly to the usual notion of provability in BBI. The (rather complicated) proof that CRM is indeed undecidable appears, we believe, only in Kurucz's Ph.D. dissertation [Kurucz 1997].
- —Another alternative proof of the undecidability of BBI was given independently by Larchey-Wendling and Galmiche [2010], which appeared at the same time as Brotherston and Kanovich [2010]. Their proof works via an embedding of BBI into a certain fragment of intuitionistic linear logic, where validity according to the standard *phase semantics* of linear logic is interpreted using a trivial closure operator. Then, they show that their considered fragment of linear logic is both undecidable and complete with respect to this trivial phase semantics. Undecidability of their fragment is based upon a specifically chosen total commutative monoid $(\mathbb{N} \times \mathbb{N}, +, (0, 0))$ and obtained via an encoding of two-counter Minsky machines (their encoding differs from ours).
- —More recently, in Larchey-Wendling and Galmiche [2013], it is additionally shown how to adapt the undecidability proof technique of Larchey-Wendling and Galmiche [2010] to the RAM-domain model (cf. Section 2.5) via bisimulation with the model $(\mathbb{N} \times \mathbb{N}, +, (0, 0))$.

In summary, our results, both here and in Brotherston and Kanovich [2010], overlap with Kurucz et al. [1995] and Larchey-Wendling and Galmiche [2010] only with respect to the individual result of undecidability of BBI (which is obtained by rather different techniques in all cases). The recent journal publication [Larchey-Wendling and Galmiche 2013] overlaps a little further in that it establishes undecidability also for validity in the RAM-domain model (which can be seen as a degenerate heap model in which cell contents, permissions, stacks, etc. are disallowed). The recent journal publication [Larchey-Wendling and Galmiche 2013] also provides an alternative way to establish undecidability for validity in the RAM-domain model (which can be seen as a degenerate heap model in which cell contents, permissions, stacks, etc. are disallowed).

There are at least three main areas in which our work is distinguished from the aforementioned work.

- (a) First, we establish the undecidability of validity for any choice of fixed memory model drawn from a spectrum of such models found in the literature, as listed in Section 2.
- (b) Second, this proof of undecidability follows from a direct encoding of Minsky machines as "sequents" of the language of separation logic. Though the primary rôle of such an encoding is purely technical, our encoding also enjoys a pedagogically instructive modular structure. Each machine instruction is encoded with a formula that clearly explains the instruction's action. The ability to reuse instructions any number of times is provided by a nontrivial proof principle which we identify as *restricted* *-*contraction*. From the point of view of our memory models, this principle semantically relies upon the fact that the empty heap can be "split" into two empty heaps.
- (c) Third, we shed light on the nature of decidable fragments of separation logic; specifically, we show that to obtain decidability either the formula language or the valuations of propositional variables must be constrained.

We remark that separation logic was conceived as a formalism to aid program verification, where typically a fixed memory model is considered. For this reason, we see the undecidability questions about validity in such models as being of primary importance. There is no *ad hoc* relationship between such problems and undecidability of validity in simpler models, or indeed undecidability of provability in BBI or related systems, which are typically incomplete.¹ Of course, it is also gratifying to be able to resolve these latter questions as a matter of historical and/or aesthetic interest. For those interested in such matters, our method does yield undecidability of BBI based on validity in arguably its simplest possible natural model: the total commutative monoid (L^+, \cup, \emptyset) , where L^+ is the set of finite multisets over a *finite* set *L*. See Section 9.5 for details.

2. MEMORY MODELS OF THEORETICAL AND PRACTICAL INTEREST

In this section, we list a series of models employing a memory-like concept that are encountered in various areas of computer science and mathematics.

2.1. Heap Models

A *heap model* [Ahmed et al. 2003; Ishtiaq and O'Hearn 2001; Reynolds 2002] is given by

 $(H, \circ, \{e\}),$

¹However, Brotherston and Villard [2014] have recently showed how to construct certain extensions of BBI based on *hybrid logic* that are complete for various classes of memory models.

where H is the set of *heaps* - that is, finite partial functions from an infinite set of *locations* L into a set of *record values* RV. The *domain* of a heap h is the finite set of locations on which h is defined.

The operation \circ is the union of heaps when their domains are disjoint, and undefined otherwise:

$$h_1 \circ h_2 = egin{cases} h_1 \cup h_2 & ext{if } h_1, h_2 ext{ have disjoint domains} \ ext{undefined} & ext{otherwise.} \end{cases}$$

The unit e of \circ is the *empty heap* - that is, the function with the empty domain.

(We represent the unit with the singleton $\{e\}$ for consistency with later models employing a *set* of units rather than a single unit.)

2.2. Stack-and-Heap Models

Stack-and-heap models, as used to model Java memory [Parkinson et al. 2006], are given by

$$(S \times H, \circ, E),$$

where H is a set of *heaps* as defined in the previous subsection, and S is a set of *stacks*, which are finite partial functions from variables Var to stack values Val.

The combination operation \circ for stack-heap pairs is defined as follows:

$$\langle s_1, h_1 \rangle \circ \langle s_2, h_2 \rangle = \begin{cases} \langle s_1, h_1 \circ h_2 \rangle & \text{if } s_1 = s_2 \text{ and } h_1 \circ h_2 \text{ is defined (by Section 2.1)} \\ \text{undefined otherwise.} \end{cases}$$

Here, the set of units *E* consists of all pairs (s, e) where $s \in S$ and *e* is the empty heap.

2.3. Heap-with-Permission Models

In heap or stack-and-heap models, enforcing the nonoverlapping of domains allows us to avoid possible "read-write" memory conflicts when combining heaps. The *heapwith-permission* models [Bornat et al. 2005] relax this strict condition; they allow overlapping heaps to be combined, providing that their values agree and "permission" for combination is permitted at all overlapping locations. Permissions are encapsulated by an underlying permission algebra

 $(P, \bullet, \mathbb{1}),$

which is a set *P* equipped with a partial, commutative, cancellative, and associative operation •, and a distinguished element 1 (the "write permission") such that $1 \bullet \pi$ is undefined for all $\pi \in P$.

Given such a permission algebra, a heap-with-permission model is then given by

 $(H, \circ, \{e\}),$

where *H* is the set of heaps-with-permissions, which are finite partial functions from an infinite set of locations *L* to a set of pairs from $RV \times P$.

We say that two such heaps h_1 and h_2 are compatible at ℓ if $h_1(\ell) = \langle v, \pi_1 \rangle$, $h_2(\ell) = \langle v, \pi_2 \rangle$ and $\pi_1 \bullet \pi_2$ is defined. If h_1 and h_2 are compatible at all ℓ from the intersection of their domains, then $h_1 \circ h_2$ is defined as follows:

$$(h_1 \circ h_2)(\ell) = \begin{cases} \langle v, \pi_1 \bullet \pi_2 \rangle & \text{if } h_1(\ell) = \langle v, \pi_1 \rangle \text{ and } h_2(\ell) = \langle v, \pi_2 \rangle \\ h_1(\ell) & \text{if } h_1(\ell) \text{ defined and } h_2(\ell) \text{ undefined} \\ h_2(\ell) & \text{if } h_1(\ell) \text{ undefined and } h_2(\ell) \text{ defined} \\ \text{undefined} & \text{otherwise.} \end{cases}$$

If h_1 and h_2 are not compatible at some common ℓ , then $h_1 \circ h_2$ is undefined. As in these heap models, the unit *e* is the heap with the empty domain.

2.4. Stack-and-Heap-with-Permission Models

Combining the stack-and-heap models of Section 2.2 with the heap-with-permission models of Section 2.3, we obtain the general class of *stack-and-heap-with-permission models* (cf. Parkinson et al. [2006]), given by

$$(S \times H, \circ, E),$$

where S is a set of stacks as defined in Section 2.2, and H is a set of heaps-withpermissions (with underlying permission algebra) as defined in Section 2.3.

The combination of stack and heap-with-permission pairs is then given by the combination operations in Sections 2.2 and 2.3 in the obvious way:

$$\langle s_1, h_1 \rangle \circ \langle s_2, h_2 \rangle = \begin{cases} \langle s_1, h_1 \circ h_2 \rangle & \text{if } s_1 = s_2 \text{ and } h_1 \circ h_2 \text{ is defined (by Section 2.3)} \\ \text{undefined otherwise.} \end{cases}$$

Again, the set of units *E* consists of all pairs (s, e) where $s \in S$ and *e* is the empty heap.

2.5. The RAM-Domain Model

In order to simplify our undecidability constructions, we consider a degenerate version of the heap model in which we remove the information contents of cells, retaining only their "address space". This model, that is "as simple as possible but no simpler", is the *RAM-domain model* of Aho et al. [1974], given by

$$(\mathcal{D}, \circ, \{e_0\}),$$

where \mathcal{D} is the class of finite subsets of \mathbb{N} , to be understood as finite sets of memory locations. The operation \circ denotes a partial operation for combining disjoint sets of locations:

$$d_1 \circ d_2 = egin{cases} d_1 \cup d_2, & ext{if } d_1 \cap d_2 = \emptyset \ ext{undefined}, & ext{otherwise}. \end{cases}$$

Here, e_0 is defined to be the neutral element or *unit* of \circ , that is, the empty set.

Remark 2.1. Any of these models can be seen as a special case of a stack-and-heapwith-permission model from Section 2.4, obtained by an appropriate choice of locations L, values RV, stacks S and permission algebra $(P, \bullet, 1)$.

2.6. Multiset/Integer Partition Models

Models related to integer partitions [Andrews 1976] are given by

$$(H,\circ,\{e_0\}),$$

where *H* is a set of finite integer multisets, with \circ being the total operation of multiset union, and the unit e_0 being the empty multiset.

2.7. Petri-Net Models

Models of *Petri-net markings* [Peterson 1981; Murata 1989] are given by

$$(H, \circ, \{e_0\}),$$

where for some $K \subseteq \mathbb{N}$ and some set *L* of *locations*, the set *H* is the set of *markings*, defined as finite partial functions from *L* into *K*.

By taking $K = \mathbb{N}$, we model states in traditional Petri nets, with \circ being the total operation of multiset union, that is, $(h_1 \circ h_2)(\ell) = h_1(\ell) + h_2(\ell)$.

By taking $K = \{0, 1, ..., k\}$, we model states in Petri nets with capacity k, where \circ is multiset union as previously mentioned, but with $(h_1 \circ h_2)(\ell)$ undefined when $h_1(\ell) + h_2(\ell) > k$.

The unit e_0 is the empty marking, that is, the marking with empty domain.

These models can be also thought of as a certain kind of memory model, where every location ℓ has an associated size or "number of blocks" $h(\ell)$.

3. PROPOSITIONAL SEPARATION LOGIC: A FORMALISM FOR REASONING ABOUT MEMORY MODELS

Here we present the language of propositional separation logic and its interpretation in the usual class of "separation models" from Calcagno et al. [2007], which abstract from the concrete memory models employed in the literature (cf. Section 2).

Definition 3.1. A separation model is a cancellative partial commutative monoid

$$(H, \circ, E),$$

where \circ is a partial binary operation on H which is associative and commutative. The equality of expressions $\alpha = \beta$ means that either α and β are both undefined, or α and β are defined and equal. Cancellativity of \circ means that if $h \circ h'$ is defined and $h \circ h' = h \circ h''$, then h' = h''.

We extend \circ to a multiplication \cdot on subsets of *H* by

$$X \cdot Y =_{\text{def}} \{ h \circ h' \mid h \in X, \ h' \in Y, \text{ and } h \circ h' \text{ is defined } \}.$$

$$(1)$$

The set of *units E* is then a subset of *H* such that, for all $h \in H$,

$$E \cdot \{h\} = \{h\}.\tag{2}$$

All the models from Section 2 are separation models. We allow a set of units E rather than a single unit e in Definition 3.1 in order to cover the whole spectrum of heap-like models (e.g., the stack-and-heap models in Section 2.2).

PROPOSITION 3.2. For any $h \in H$, there is a unique element $e \in E$ such that $h \circ e = h$.

PROOF. The existence of a suitable *e* is guaranteed by $h \circ E = \{h\}$. For uniqueness, assume $h \circ e = h \circ e' = h$. Then, by cancellativity, we get e = e'. \Box

PROPOSITION 3.3. The set of units E in a separation model (H, \circ, E) forms a "unit matrix". That is, for any $e_i, e_j \in E$, we have:

$$e_i \circ e_j = \begin{cases} e_i, & \text{if } e_i = e_j, \\ undefined, & otherwise. \end{cases}$$

In particular, if \circ is total, then *E* is forced to be a singleton $\{e\}$.

PROOF. Let $e_i, e_j \in E$. Using (2) and commutativity of \circ , we have $\{e_i\} \cdot E = \{e_i\}$ whence $e_i \circ e_j$ is either e_i or undefined. But, by the same token, $E \cdot \{e_j\} = \{e_j\}$ whence $e_i \circ e_j$ is either e_j or undefined. Thus, if $e_i \neq e_j$, then $e_i \circ e_j$ must be undefined. To see that $e_i \circ e_i = e_i$, observe that we must have $e_i \circ e = e_i$ for some $e \in E$ because $e_i \in \{e_i\} \cdot E$. \Box

Definition 3.4. A separation model (H, \circ, E) is said to have *indivisible units* if $h_1 \circ h_2 \in E$ implies $h_1 \in E$ and $h_2 \in E$ for all $h_1, h_2 \in H$.

(In fact, in this case $h_1 = h_2$ because of the observation in Proposition 3.3 that $h_1 \circ h_2$ must be undefined when $h_1 \neq h_2$.)

Remark 3.5. The memory models employed in the literature (see Section 2) all have indivisible units in the sense of Definition 3.4. This natural property can be summarised by the following slogan on "conservation of matter":

"The empty memory cannot be split into non-empty pieces".

However, in contrast to the memory models, we can easily construct a separation model whose units are divisible; for example, the model $(\mathbb{Z}, +, \{0\})$, where + is addition on the integers \mathbb{Z} , is one such.

Definition 3.6. *Formulas* are built from an infinite set of atomic propositions p and constants \top , \bot , and I, by a unary operator \neg and binary connectives \land , \lor , \rightarrow , *, and -*. (We call * the *multiplicative conjunction*, with -* its associated *adjoint implication* and I its *unit*.)

For the sake of readability, we often write a formula of the form $A \rightarrow B$ as the "sequent" $A \vdash B$.

By convention, negation \neg has the greatest precedence, followed by \land , \lor , and *, with the implications \rightarrow and -* having lowest precedence.

Definition 3.7. A valuation for a separation model (H, \circ, E) is a function ρ that assigns to each atomic proposition p a set $\rho(p) \subseteq H$. Given any $h \in H$ and formula A, we define the forcing relation $h \models_{\rho} A$ by induction on A:

$$\begin{split} h &\models_{\rho} p \iff h \in \rho(p) \\ h &\models_{\rho} \top \iff \text{always} \\ h &\models_{\rho} \bot \iff \text{never} \\ h &\models_{\rho} \neg A \iff h \not\models_{\rho} A \\ h &\models_{\rho} A_{1} \land A_{2} \iff h \models_{\rho} A_{1} \text{ and } h \models_{\rho} A_{2} \\ h &\models_{\rho} A_{1} \land A_{2} \iff h \models_{\rho} A_{1} \text{ or } h \models_{\rho} A_{2} \\ h &\models_{\rho} A_{1} \lor A_{2} \iff h \models_{\rho} A_{1} \text{ or } h \models_{\rho} A_{2} \\ h &\models_{\rho} A_{1} \Rightarrow A_{2} \iff \text{if } h \models_{\rho} A_{1} \text{ then } h \models_{\rho} A_{2} \\ h &\models_{\rho} I \iff h \in E \\ h &\models_{\rho} A_{1} \Rightarrow A_{2} \iff \exists h_{1}, h_{2}. h = h_{1} \circ h_{2} \text{ and } h_{1} \models_{\rho} A_{1} \text{ and } h_{2} \models_{\rho} A_{2} \\ h &\models_{\rho} A_{1} \Rightarrow A_{2} \iff \forall h', \text{ if } h \circ h' \text{ defined and } h' \models_{\rho} A_{1} \text{ then } h \circ h' \models_{\rho} A_{2}. \end{split}$$

The intended meaning of any formula A under ρ is given by

$$\llbracket A \rrbracket_{\rho} =_{\text{def}} \{ h \mid h \models_{\rho} A \}.$$

LEMMA 3.8. Given a separation model (H, \circ, E) and a valuation ρ for the model, we have the following identities:

$$\llbracket p \rrbracket_{\rho} = \rho(p) \tag{3}$$

$$\llbracket \bot \rrbracket_{\rho} = \emptyset \tag{4}$$

$$[\mathbf{I}]]_{\rho} = E \tag{5}$$

$$\llbracket A \wedge B \rrbracket_{\rho} = \llbracket A \rrbracket_{\rho} \cap \llbracket B \rrbracket_{\rho} \tag{6}$$

$$\llbracket A * B \rrbracket_{\rho} = \llbracket A \rrbracket_{\rho} \cdot \llbracket B \rrbracket_{\rho} \tag{7}$$

$$\llbracket A \to B \rrbracket_{\rho} = largest \ Z \subseteq H. \ \llbracket A \rrbracket_{\rho} \cap Z \subseteq \llbracket B \rrbracket_{\rho}$$
(8)

$$\llbracket A \twoheadrightarrow B \rrbracket_{\rho} = largest \ Z \subseteq H. \ \llbracket A \rrbracket_{\rho} \cdot Z \subseteq \llbracket B \rrbracket_{\rho}.$$
⁽⁹⁾

PROOF. We just show the identities (7) and (9). In the case of (7), we have:

$$\llbracket A * B \rrbracket_{\rho} = \{ h \mid \exists h_1, h_2. h = h_1 \circ h_2 \text{ and } h_1 \models_{\rho} A \text{ and } h_2 \models_{\rho} B \}$$

= $\{ h_1 \circ h_2 \mid h_1 \models_{\rho} A \text{ and } h_2 \models_{\rho} B \text{ and } h_1 \circ h_2 \text{ defined} \}$
= $\{ h_1 \circ h_2 \mid h_1 \in \llbracket A \rrbracket_{\rho} \text{ and } h_2 \in \llbracket B \rrbracket_{\rho} \text{ and } h_1 \circ h_2 \text{ defined} \}$
= $\llbracket A \rrbracket_{\rho} \cdot \llbracket B \rrbracket_{\rho}.$

J. Brotherston and M. Kanovich

14:10

To show (9), we first show that $[A \twoheadrightarrow B]_{\rho}$ satisfies the required inclusion, that is

$$\llbracket A \rrbracket_{\rho} \cdot \llbracket A \twoheadrightarrow B \rrbracket_{\rho} \subseteq \llbracket B \rrbracket_{\rho}.$$

To see this, let $h \in \llbracket A \rrbracket_{\rho} \cdot \llbracket A \twoheadrightarrow B \rrbracket_{\rho}$. Then there are $h_1, h_2 \in H$ with $h = h_1 \circ h_2$ and $h_1 \models_{\rho} A$ and $h_2 \models_{\rho} A \twoheadrightarrow B$. In particular, this means that for any h' such that $h' \circ h_2$ is defined and $h' \models_{\rho} A$, we have $h' \circ h_2 \models_{\rho} B$. Since $h_1 \circ h_2$ is defined, we have $h_1 \circ h_2 \models_{\rho} B$, that is, $h \models_{\rho} B$ as required.

To see that $\llbracket A \twoheadrightarrow B \rrbracket_{\rho}$ is the *largest* set satisfying the required inclusion, we let $Z \subseteq H$ satisfy $\llbracket A \rrbracket_{\rho} \cdot Z \subseteq \llbracket B \rrbracket_{\rho}$, and show that $Z \subseteq \llbracket A \twoheadrightarrow B \rrbracket_{\rho}$. This means showing that if $h \in Z$, then $h \models_{\rho} A \twoheadrightarrow B$. Let $h' \in H$ be such that $h \circ h'$ is defined and $h' \models_{\rho} A$, that is, $h' \in \llbracket A \rrbracket_{\rho}$. Since $\llbracket A \rrbracket_{\rho} \cdot Z \subseteq \llbracket B \rrbracket_{\rho}$, we have $h \circ h' \in \llbracket B \rrbracket_{\rho}$, that is, $h \circ h' \models_{\rho} B$ as required. \Box

Definition 3.9. A formula *A* is *valid* in a separation model (H, \circ, E) if for any valuation ρ , we have $[\![A]\!]_{\rho} = H$.

In particular, a sequent $A \vdash B$ is valid in (H, \circ, E) if $\llbracket A \rrbracket_{\rho} \subseteq \llbracket B \rrbracket_{\rho}$ for any valuation ρ .

In the next theorem, we establish the exact correlation between seemingly different concepts: the *indivisibility of units* in the memory models, and the *restricted *-weakening* in formal systems, given by axioms of the form

$$\mathbf{I} \wedge (A \ast B) \vdash A.$$

Тнеогем 3.10.

(a) For any formulas A and B, the restricted *-weakening principle

 $\mathbf{I} \wedge (A \ast B) \vdash A$

is valid in all separation models (H, \circ, E) with indivisible units.

(b) In addition, the above correlation is exact. Namely, the basic instance of the restricted *-weakening principle (here p and q are atomic propositions),

 $\mathbf{I} \wedge (p * q) \vdash p$,

is valid in a separation model (H, \circ, E) if and only if (H, \circ, E) has indivisible units.

PROOF.

- (a) Let (H, ◦, E) be a separation model with indivisible units, let h ∈ H and suppose that h ⊨_ρ I ∧ (A ∗ B). Thus, h ∈ E and there exist h₁, h₂ ∈ H with h = h₁ h₂ and h₁ ⊨_ρ A and h₂ ⊨_ρ B. As (H, ◦, E) has indivisible units, we have h₁ ∈ E and h₂ ∈ E, whence by Proposition 3.3, we have h₁ = h₂ = h. Thus, h ⊨_ρ A and, as h was arbitrarily chosen, I ∧ (A ∗ B) ⊢ A is valid in this model as required.
- (b) Let (H', \circ', E) be a separation model whose set of units E is divisible, that is, such that $h' \circ' h'' = e \in E$ for some $h' \notin E$.

Let ρ be a valuation with $\rho(p) = \{h'\}$ and $\rho(q) = \{h''\}$. Then, we easily have that $e \models_{\rho} I \land (p * q)$ but $e \not\models_{\rho} p$, so $I \land (p * q) \vdash p$ is not valid in this model as required. \Box

The following proposition shows that separation models with total and nontotal compositions \circ behave quite differently with respect to validity.

PROPOSITION 3.11. A sequent of the form

$$\mathbf{I} \wedge (p \ast q \twoheadrightarrow \bot) \vdash (p \twoheadrightarrow \bot) \vee (q \twoheadrightarrow \bot) \tag{10}$$

is valid in a separation model (H, \circ, E) if and only if the operation \circ is total.

PROOF. In fact, the sequent (10) represents the following "natural" law:

 $\llbracket p \rrbracket_{\rho} \cdot \llbracket q \rrbracket_{\rho} = \emptyset \text{ implies } (\llbracket p \rrbracket_{\rho} = \emptyset \text{ or } \llbracket q \rrbracket_{\rho} = \emptyset).$

 (\Leftarrow) Let (H, \circ, E) be a separation model with \circ total, and suppose $h \models_{\rho} I \land (p * q \twoheadrightarrow \bot)$. Then, $h \in E$ and $h \models_{\rho} p * q \twoheadrightarrow \bot$. Using Lemma 3.8, we have $[\![p * q]\!]_{\rho} \subseteq [\![\bot]\!]_{\rho} = \emptyset$, and thus $[\![p]\!]_{\rho} \cdot [\![q]\!]_{\rho} = [\![p * q]\!]_{\rho} = \emptyset$.

Since \circ is total, $\llbracket p \rrbracket_{\rho} \cdot \llbracket q \rrbracket_{\rho} = \emptyset$ implies that either $\llbracket p \rrbracket_{\rho} = \emptyset$ or $\llbracket q \rrbracket_{\rho} = \emptyset$. Consequently, either $h \models_{\rho} p \twoheadrightarrow \bot$ or $h \models_{\rho} q \twoheadrightarrow \bot$, i.e. $h \models_{\rho} (p \twoheadrightarrow \bot) \lor (q \twoheadrightarrow \bot)$ as required.

 (\Rightarrow) Let (H, \circ, E) be a separation model in which \circ is nontotal, that is for some h' and h'', their product $h' \circ h''$ is undefined. Let ρ be a valuation with $\rho(p) = \{h'\}$ and $\rho(q) = \{h''\}$. Then, $[\![p]\!]_{\rho} \cdot [\![q]\!]_{\rho} = \emptyset$ by construction. Thus, using Lemma 3.8, we have

$$egin{aligned} E \cdot \llbracket p st q
rbracket_
ho &= \llbracket p st q
rbracket_
ho \ &= \llbracket p
rbracket_
ho \cdot \llbracket q
rbracket_
ho \ &= artheta \ &= artheta$$

Thus, in particular, $E \cdot [\![p * q]\!]_{\rho} \subseteq [\![\bot]\!]_{\rho}$ and, by Lemma 3.8, we have $E \subseteq [\![p * q \twoheadrightarrow \bot]\!]_{\rho}$, which means that $[\![I \land (p * q \twoheadrightarrow \bot)]\!]_{\rho} \neq \emptyset$. On the other hand, by construction, both $[\![p \twoheadrightarrow \bot]\!]_{\rho} = \emptyset$ and $[\![q \twoheadrightarrow \bot]\!]_{\rho} = \emptyset$, that is, $[\![(p \twoheadrightarrow \bot) \lor (q \twoheadrightarrow \bot)]\!]_{\rho} = \emptyset$. We conclude that our sequent is not valid in this model as required. \Box

4. FORMAL SYSTEMS FOR SEPARATION LOGIC

In this section, we explore various notions of *provability* in the language of propositional separation logic, and examine their connection to validity in various classes of models. First, in Section 4.1, we introduce the core axiomatisation of the multiplicative connectives *, -* and I. Then, in Section 4.2, we examine a chain of logical systems extending this axiomatisation, including the well-known *bunched logics* BI and Boolean BI.

4.1. Axiomatisation of the Multiplicatives

The mathematical behaviour of separation models (H, \circ, E) (see Definition 3.1), and the interpretation of the multiplicative connectives *, -* and I (Definition 3.7) naturally gives rise to a number of axioms and rules for these connectives, as follows.

(a) First, the combination operation \circ is associative and commutative by definition, which means that the multiplicative conjunction * should also be associative and commutative:

$$A * B \vdash B * A$$
 and $A * (B * C) \vdash (A * B) * C$.

(b) Next, the set *E* is a unit for \circ , that is, $E \circ \{h\} = \{h\}$, which means that I (representing *E*) should also be a unit for *:

$$A * I \vdash A$$
 and $A \vdash A * I$.

(c) The "magic wand" connective -* is defined as the implication adjoint to the conjunction *, which leads to the following residuation principles for * and -*:

$$A * (A \twoheadrightarrow B) \vdash B$$
 and $\frac{A * B \vdash C}{A \vdash B \twoheadrightarrow C}$.

(d) Finally, we have the following monotonicity or "frame" principle for building entailments between *-conjunctions:

$$\frac{A \vdash B}{A * C \vdash B * C}$$

In fact, this collection of axioms and inference rules for the multiplicatives is originally provided by intuitionistic multiplicative linear logic, IMLL [Girard and Lafont 1987; Benton et al. 1993].

4.2. Bunched Logic Proof Systems for Separation Logic

Core proof systems for propositional separation logic are provided by *bunched logic*, a class of substructural logics pioneered by O'Hearn and Pym. Specifically, the propositional proof theory of separation logic is usually considered to be given by the bunched logic Boolean BI, although other choices are also possible. Every separation model can be seen as a model of Boolean BI [Ishtiaq and O'Hearn 2001; Galmiche and Larchey-Wendling 2006].

Definition 4.1. We consider the following chain of logical systems

$$BI \subseteq BBI \subseteq BBI + eW \subseteq BBI + W,$$

each defined as follows:

-BI, a.k.a. the *logic of bunched implications* (cf., O'Hearn and Pym [1999], Pym [2002], and Galmiche et al. [2005]) is given by:

(A) all instances of intuitionistically valid formulas and inference rules, and

(B) the axioms and inference rules for *, -* and I given in Section 4.1.

-Boolean BI, a.k.a. BBI (cf., Ishtiaq and O'Hearn [2001] and Galmiche and Larchey-Wendling [2006]) is obtained from BI by expanding (A) above to include all instances of *classically* valid propositional formulas and inference rules.

-As we shall see (Lemma 6.4), the *restricted* *-*contraction*

 $\mathbf{I} \wedge A \vdash A * A$

holds in BBI, whereas the analogous restricted \ast -weakening

$$\mathrm{I} \land (A \ast B) \vdash A$$

does not. However, the restricted *-weakening exactly expresses the indivisibility of units in a separation model (see Theorem 3.10). Thus, we introduce the system BBI+eW by enriching BBI with all new axioms of the form $I \land (A * B) \vdash A$.

-Having considered restricted *-weakening, it is also natural to consider BBI+W, obtained by enriching BBI with the *unrestricted* *-*weakening* - that is, axioms of the form

 $A * B \vdash A$

(or, equivalently, $B \vdash I$).

PROPOSITION 4.2 (Soundness of BBI). If A is provable in BBI, then A is valid in all separation models.

Proof. We just need to show that validity in any separation model is preserved by the axioms and rules of classical propositional logic and by the axioms and rules given in Section 4.1, which is an easy exercise. \Box

In many cases, the connection between provability in the systems in Definition 4.1 and validity in the classes of corresponding separation models is not exact. For example, BBI is not complete even for validity in the class of all partial commutative monoids [Larchey-Wendling and Galmiche 2010]. No complete natural axiomatisation

is currently known for validity with respect to the class of all separation models (or an interesting subclass thereof).

COROLLARY 4.3 (SOUNDNESS OF BBI+eW). If A is provable in BBI+eW, then A is valid in all separation models with indivisible units.

PROOF. Immediate from Proposition 4.2 and Theorem 3.10. \Box

COROLLARY 4.4. Interpreting \subset as strict inclusion between the sets of sequents provable in each system, we have:

$$BI \subset BBI \subset BBI + eW \subset BBI + W.$$

PROOF. First, note that the non-strict inclusions $BI \subseteq BBI \subseteq BBI + eW \subseteq BBI + W$ hold easily by the construction of the systems in Definition 4.1. Thus, we just need to show $BBI+W \not\subseteq BBI + eW \not\subseteq BBI \not\subseteq BI$.

First, BBI $\not\subseteq$ BI holds because BI is conservative over intuitionistic logic [Pym 2002] and thus, for example, the classical tautology $(p \rightarrow \bot) \rightarrow \bot \vdash p$ is invalid in BI, whereas it is valid in BBI.

BBI+eW $\not\subseteq$ BBI holds because, by Theorem 3.10, the instance $I \land (p * q) \vdash p$ of BBI+eW's restricted *-weakening axiom is not valid in all separation models, and hence not provable in BBI by Proposition 4.2.

Finally, BBI+W $\not\subseteq$ BBI+eW holds because the instance $p \vdash I$ of BBI+W's unrestricted *-weakening axiom is not valid in all separation models with indivisible units, and hence not provable in BBI+eW by Corollary 4.3. To see this, let (H, \circ, E) be a separation model with indivisible units, and let $\rho(p) = \{h\}$ for some $h \notin E$. Then, easily, $h \models_{\rho} p$ but $h \not\models_{\rho} I$. \Box

One of the important features of separation logic is that the *-contraction, $A \vdash A * A$, is not generally valid, and hence not provable in BBI by Proposition 4.2. Surprisingly, however, BBI does enjoy the *restricted* *-contraction (see Lemma 6.4 in Section 6)

$$I \wedge A \vdash A * A$$
,

which holds only at the level of the multiplicative unit I.

Remark 4.5. We note that the following basic instance of restricted *-contraction

$$I \land p \vdash p * p$$

is not valid in ordinary intuitionistic BI. This can most easily be seen from the elementary Kripke semantics of BI in Galmiche et al. [2005], whereby models are ordered partial commutative monoids $(M, \circ, e, \sqsubseteq)$, and we have the following clauses for satisfaction of formulas by $m \in M$ and valuation ρ :

$$m \models_{\rho} \mathbf{I} \Leftrightarrow e \sqsubseteq m$$

 $m \models_{\rho} A \land B \Leftrightarrow m \models_{\rho} A \text{ and } m \models_{\rho} B.$
 $m \models_{\rho} A * B \Leftrightarrow \exists n, n' \in M. \ n \circ n' \le m \text{ and } n \models_{\rho} A \text{ and } n \models_{\rho} B$

Now consider the 2-element BI-model

$$(\{e, b\}, \circ, e, \sqsubseteq),$$

where \circ is given by $e \circ e = b \circ b = e$ and $e \circ b = b \circ e = b$, and \sqsubseteq is given by $e \sqsubset b$. Let ρ be a valuation with $\rho(p) = \{b\}$. Then, easily, $b \models_{\rho} I \land p$ but $b \not\models_{\rho} p * p$, that is, $I \land p \vdash p * p$ is not valid in this model.²

²The key difference compared to validity in separation models is that, in the satisfaction relation for BBI in Definition 3.7, $b \models_{\rho} I \land p$ forces e = b, while in the satisfaction relation for BI, it only forces $e \sqsubseteq b$.

In the case of BBI+eW, its restricted *-weakening with the restricted *-contraction of Lemma 6.4 induces a collapse of \land and * at the level of the unit I, as follows.

COROLLARY 4.6. The following equivalences hold in BBI+eW:

$$\mathbf{I} \wedge (A \ast B) \equiv \mathbf{I} \wedge A \wedge B \equiv (\mathbf{I} \wedge A) \ast (\mathbf{I} \wedge B),$$

where the equivalence $F \equiv G$ means that both $F \vdash G$ and $G \vdash F$ are provable.

PROOF. First, $I \land (A * B) \vdash I \land A \land B$ is derivable using the restricted *-weakening. Second, using the restricted *-contraction and the usual contraction for \land we can derive:

$$\mathbf{I} \wedge A \wedge B \vdash (\mathbf{I} \wedge A \wedge B) * (\mathbf{I} \wedge A \wedge B),$$

whence $I \land A \land B \vdash (I \land A) * (I \land B)$ follows from weakening for \land . Finally, we can derive $(I \land A) * (I \land B) \vdash I \land (A * B)$ using the equivalence $I * C \equiv C$ and weakening for \land . The required equivalences then follow by transitivity of \vdash . \Box

PROPOSITION 4.7. BBI+W collapses into ordinary classical logic.

PROOF. Trivially, $I \land A \vdash A$ is provable in BBI+W. Using the equivalence $I * A \equiv A$ and contraction for \land , we also have $A \vdash (I * A) \land A$ provable. Using the unrestricted *-weakening of BBI+W, we obtain $A \vdash I \land A$, and thus $I \land A \equiv A$ holds in BBI+W. Using this equivalence together with Corollary 4.6, we have:

$$A * B \equiv I \land (A * B) \equiv I \land A \land B \equiv A \land B,$$

which also guarantees that $A \twoheadrightarrow B \equiv A \rightarrow B$. Finally, using the equivalence $I \land A \equiv A$, we have $I \equiv I \land \top \equiv \top$. Thus, all the multiplicative connectives of BBI+W collapse into their classical additive equivalents. \Box

Remark 4.8. Both ends of the chain of logics $BI \subset BBI \subset BBI+eW \subset BBI+W$ given by Corollary 4.4 are in fact *decidable*. BI was shown decidable in Galmiche et al. [2005], and BBI+W is decidable because, by Proposition 4.7, it collapses into ordinary classical logic. Thus, technically speaking, it is relatively surprising that—as we shall see in the next section—the intermediate systems BBI and BBI+eW are both in fact *undecidable*.

5. UNDECIDABILITY OF PROPOSITIONAL FORMULAS FOR THE MEMORY MODELS

In this section, we give a high-level outline of our undecidability results and their proof, the details of which occupy most of the remainder of the article.

Figure 1 shows the overall development of our proof. As is typical, we show that a property Q is undecidable by showing that a problem already known to be undecidable reduces to the problem of deciding Q. In our case, the undecidable problem to be encoded is the termination of a two-counter, non-deterministic Minsky machine M from an arbitrary configuration C, shown as the top-centre node in Figure 1.

The proof strategy then goes as follows.

We encode M and C as a formula $\mathcal{F}_{M,C}$ (defined in Section 7) such that termination of M from C implies that $\mathcal{F}_{M,C}$ is provable in BBI (Theorem 8.3). In fact, we can obtain this result even for a *minimal* version of BBI whose Boolean connectives are restricted to \wedge and \rightarrow : in particular, negation \neg and falsum \bot are disallowed. We present this "Minimal BBI" in Section 6.

By construction of the proof systems in Definition 4.1, provability of $\mathcal{F}_{M,C}$ in Minimal BBI implies its provability in BBI and BBI+eW. By our soundness results (Proposition 4.2 and Corollary 4.3) this implies validity of $\mathcal{F}_{M,C}$ in the class of all separation models, and in the class of all separation models with indivisible units, respectively. Specifically, $\mathcal{F}_{M,C}$ must be valid in *any particular* model chosen from those in Section 2.

Fig. 1. Diagrammatic proof of undecidability. The arrows are implications, and $\mathcal{F}_{M,C}$ is a sequent built from machine *M* and configuration *C*. The problems at each node are all undecidable.

Finally, we can complete the circle of implications—and thus the reduction from the halting problem for Minsky machines—by establishing that validity of $\mathcal{F}_{M,C}$ in any particular such model implies that the machine M terminates from configuration C. This is established by Theorem 9.11.

As a consequence, every property of formulas between provability in Minimal BBI and validity in one of the models from Section 2 is undecidable.

The right-hand side of Figure 1 essentially repeats this proof structure, but for *Classical* BI (CBI) and its models, which obey stronger properties than BBI and its separation models. Classical BI, its models and the corresponding undecidability results are presented in Section 11.

COROLLARY 5.1. The following properties of formulas are undecidable, even when restricted to the language $(\land, \rightarrow, I, *, -*)$ of Minimal BBI:

- (a) provability in Minimal BBI;
- (b) provability in BBI;
- (c) provability in BBI+eW;
- (d) validity in the class of all separation models;
- (e) validity in the class of all separation models with indivisible units;
- (f) validity in the class of all total separation models;
- (g) validity in the class of all total separation models with indivisible units;

 $\begin{array}{ll} (\alpha_{1}) & A \ast B \vdash B \ast A & (\alpha_{4}) & A \ast I \vdash A \\ (\alpha_{2}) & A \ast (B \ast C) \vdash (A \ast B) \ast C & (\alpha_{5}) & A \vdash A \ast I \\ (\alpha_{3}) & A \ast (A \multimap B) \vdash B & \\ & \frac{A \vdash B}{A \ast C \vdash B \ast C} (\alpha_{6}) & \frac{A \ast B \vdash C}{A \vdash (B \multimap C)} (\alpha_{7}) \\ (\beta_{1}) & A \vdash (B \to A) & (\beta_{4}) & A \vdash (B \to (A \land B)) \\ (\beta_{2}) & (A \to (B \to C)) \vdash ((A \to B) \to (A \to C)) & (\beta_{5}) & A \land B \vdash A \\ (\beta_{3}) & ((A \to B) \to A) \vdash A & (Peirce's law) & (\beta_{6}) & A \land B \vdash B \\ & \frac{A \sqcup B}{B} (MP) \end{array}$

Fig. 2. A minimal set of axioms and rules for Minimal Boolean BI. The axioms and rules labelled (α_i) axiomatize the behaviour of I, * and \rightarrow , while the axioms and rules labelled (β_i) axiomatize \land and \rightarrow .

(h) validity in one of the concrete models in Section 2, for arbitrarily chosen locations L, values RV, stacks S, and permission algebra $(P, \bullet, 1)$ (note L must be infinite).

PROOF. The termination problem for Minsky machines, which is undecidable [Minsky 1967], reduces to each of the problems above by the diagram in Figure 1. \Box

COROLLARY 5.2. Neither Minimal BBI nor BBI nor BBI+eW has the finite model property.

PROOF. A recursive enumeration of proofs and finite countermodels for any of the logics above would yield a decision procedure for provability, which is impossible. \Box

6. MINIMAL BOOLEAN BI - A VERY SIMPLE UNDECIDABLE PROPOSITIONAL SYSTEM

One might be tempted to think that the undecidability of BBI, in particular, is mainly an artifact of Boolean negation, which is its most visible point of difference to standard (intuitionistic) BI. In fact, this is not the case. In this section we introduce a minimal positive fragment of BBI, called *Minimal* BBI, in which the formula connectives are restricted to the minimal set of \land , \rightarrow , I, * and \neg *. Minimal BBI is given by the axioms and rules in Figure 2, which extend the axioms and rules for *, \neg * and I in Section 4 (here labelled (α_i)) with minimal rules and axioms for \rightarrow and \land (labelled (β_i)).

Remark 6.1. As foreshadowed in the previous section, Minimal BBI, even though it looks extremely simple, is still *undecidable*, notwithstanding the fact that both its components are decidable: the implication-conjunction fragment of Boolean logic is co-NP-complete, and intuitionistic multiplicative linear logic is NP-complete [Kanovich 1992].

Oddly enough, removing *Peirce's law* from Figure 2 results in (a restricted version of) standard intuitionistic BI, which is decidable. This is quite counterintuitive, since by removing Peirce's law we replace the simple Boolean logic component in Figure 2 (given by the β axioms and the MP rule) with the implication-conjunction fragment of intuitionistic logic, the complexity of which is higher (being PSPACE-complete [Statman 1979]).

Note that in Figure 2 we must include the axioms and rules for \land , since \land itself is not definable exclusively in terms of \rightarrow . Also, neither \neg nor \bot is expressible by \land and \rightarrow alone. As a consequence, it is necessary to establish that various expected principles of classical logic, present in full BBI by construction, still hold in Minimal BBI.

Definition 6.2. As for *disjunction*, here, and henceforth, we will conceive of $(A \lor B)$ as an *abbreviation* for $((B \to A) \to A)$.

PROPOSITION 6.3. The following inference rules are derivable in Minimal BBI.

$$\frac{A \vdash B \quad B \vdash C}{A \vdash C} (\mathrm{Tr}) \qquad \frac{A \vdash B \quad A \vdash C}{A \vdash C} (\mathrm{Tr}) \qquad \frac{A \vdash B \quad A \vdash C}{A \vdash B \land C} (\wedge)$$

$$\frac{A \vdash (B \to C)}{A \land B \vdash C} (\to) \qquad \frac{A \vdash (B \to C)}{A \ast B \vdash C} (-\ast) \qquad \frac{B \vdash C}{\mathrm{I} \vdash (B \to C)} (\mathrm{I})$$

$$\frac{A \vdash B}{B \to C \vdash A \to C} (\mathrm{MT}) \qquad \frac{A \vdash C \quad B \vdash C}{A \lor B \vdash C} (\vee) \qquad \frac{A \vdash C \quad (A \to B) \vdash C}{C} (\mathrm{EM})$$

Moreover, the rules (\rightarrow) , $(\neg \ast)$ and (I) are all reversible, that is, their premise and conclusion are interchangeable.

PROOF. We show how to derive each proof rule directly by the standard technique. In the following, recall that the sequent $A \vdash B$ is merely another notation for the formula $A \rightarrow B$.

(Id). By instantiating the axioms (β_1) and (β_2) we obtain, respectively,

$$A \vdash ((A \to A) \to A)$$
$$(A \to ((A \to A) \to A)) \vdash ((A \to (A \to A)) \to (A \to A)).$$

Thus, by (MP), we obtain $(A \to (A \to A)) \vdash (A \to A)$. Thus, since $A \vdash (A \to A)$ is an instance of (β_1) , we obtain $A \vdash A$ by (MP).

(Tr). We have $B \vdash C$ provable by assumption and $(B \to C) \vdash (A \to (B \to C))$ an instance of (β_1) . Thus, by (MP), we obtain $A \to (B \to C)$. Now by instantiating the axiom (β_2) we obtain:

$$(A \to (B \to C)) \vdash ((A \to B) \to (A \to C)),$$

whence by (MP) we obtain $(A \rightarrow B) \vdash (A \rightarrow C)$. Then, since $A \vdash B$ is provable by assumption we obtain $A \vdash C$ by (MP) again as required.

(\wedge). We have $A \vdash B$ by assumption and $B \vdash (C \rightarrow B \land C)$ an instance of (β_4) . Thus, by (Tr), we obtain $A \vdash (C \rightarrow B \land C)$. Now, by instantiating (β_2) we have:

$$(A \to (C \to B \land C)) \vdash ((A \to C) \to (A \to B \land C)).$$

Hence, by (MP), we obtain $(A \rightarrow C) \vdash (A \rightarrow B \land C)$. Since we have $A \vdash C$, by assumption, we obtain $A \vdash B \land C$ by (MP) as required.

 (\rightarrow) . For the top-to-bottom direction, note that we have $A \wedge B \vdash A$ an instance of (β_5) and $A \vdash (B \rightarrow C)$ provable by assumption. Thus, by (Tr), we obtain $A \wedge B \vdash (B \rightarrow C)$. Now, by instantiating (β_2) , we have:

$$(A \land B \to (B \to C)) \vdash ((A \land B \to B) \to (A \land B \to C)).$$

Hence, by (MP), we obtain $(A \land B \to B) \vdash (A \land B \to C)$. Since $A \land B \vdash B$ is an instance of (β_6), we can apply (MP) again to obtain $A \land B \vdash C$ as required.

For the bottom-to-top direction, we have $A \land B \vdash C$ by assumption. Thus, using (β_1) and (Tr), we obtain $B \vdash (A \land B \rightarrow C)$. By instantiating (β_2) , we have

$$B \to ((A \land B) \to C) \vdash ((B \to A \land B) \to (B \to C)).$$

Hence, by (MP), we obtain $(B \to A \land B) \vdash (B \to C)$. Applying (β_1) and (Tr) again, this gives us $A \vdash ((B \to A \land B) \to (B \to C))$. Now we have as a further instantiation of (β_2)

$$A \to ((B \to A \land B) \to (B \to C)) \vdash ((A \to (B \to A \land B)) \to (A \to (B \to C))).$$

Hence, by (MP), we obtain

$$(A \to (B \to A \land B)) \vdash (A \to (B \to C)).$$

As $A \vdash B \to A \land B$ is an instance of (β_4) , we obtain $A \vdash B \to C$ by (MP) as required.

- (-*). The bottom-to-top direction is immediate by (α_7) . For the top-to-bottom direction, since $A \vdash (B \twoheadrightarrow C)$ is provable by assumption, we have $A * B \vdash (B \twoheadrightarrow C) * B$ by the rule (α_6) . Since $(B \twoheadrightarrow C) * B \vdash B * (B \twoheadrightarrow C)$ is an instance of (α_1) , we then obtain $A * B \vdash B * (B \twoheadrightarrow C)$ by (Tr). Then, since $B * (B \twoheadrightarrow C) \vdash C$ is an instance of (α_3) , we can apply (Tr) again to obtain $A * B \vdash C$ as required.
- (I). For the top-to-bottom direction, we have $B * I \vdash B$ an instance of (α_4) and $I * B \vdash B * I$ an instance of (α_1) whence $I * B \vdash B$ is provable by (Tr). Since $B \vdash C$ is provable by assumption, we obtain $I * B \vdash C$ by (Tr), whence $I \vdash (B \twoheadrightarrow C)$ is provable using the rule (-*). The reverse direction is similar.
- (MT). (This rule is named for being "modus tollens-like".) First, $(B \to C) \vdash (B \to C)$ is derivable using (Id). Thus, by the rule (\to) , together with (Tr) and commutativity of \land (easily derivable from the rule (\land)), we obtain $B \vdash ((B \to C) \to C)$. Since we have $A \vdash B$ by assumption, we obtain $A \vdash ((B \to C) \to C)$ by (Tr). Thus, by applying the deduction theorem again, together with commutativity of \land and (Tr), we have $(B \to C) \vdash (A \to C)$ as required.
- (\lor). Since we have $B \vdash C$ by assumption, we can obtain by applying the rule (MT) twice

$$((B \to A) \to A) \vdash ((C \to A) \to A).$$

By applying the rule (\rightarrow) , we then obtain $(B \rightarrow A) \rightarrow A) \land (C \rightarrow A) \vdash A$. Since $A \vdash C$ is provable by assumption, we obtain $(B \rightarrow A) \rightarrow A) \land (C \rightarrow A) \vdash C$ by applying (Tr). By applying (\rightarrow) again, we have

$$((B \to A) \to A) \vdash ((C \to A) \to C).$$

Now we have $((C \to A) \to C) \vdash C$ an instance of Peirce's law (β_3) . Thus, we obtain $((B \to A) \to A) \vdash C$ by (Tr), which is abbreviated by $A \lor B \vdash C$.

(EM). (This rule is named for being "excluded middle-like".) We have by assumption $A \vdash C$ and $(A \rightarrow B) \vdash C$, so we obtain $A \lor (A \rightarrow B) \vdash C$ by applying the rule (\lor) . By definition, $A \lor (A \rightarrow B)$ is equal to $((A \rightarrow B) \rightarrow A) \vdash A$, which is an instance of Peirce's law (α_3) . Thus, we obtain *C* by (MP). \Box

We remark that the rules (\land) and (\lor) given by Proposition 6.3 immediately imply the associativity and commutativity of \land and \lor , whereas associativity and commutativity of \ast is directly expressed by axioms (α_1) and (α_2) of Minimal BBI. From now on, when we work in Minimal BBI, we implicitly treat \land , \lor , and \ast as being commutative and associative.

As mentioned in Section 4, the *restricted* *-*contraction* given by $I \land A \vdash A * A$ holds in BBI, and in fact it holds even in Minimal BBI, which is of utmost importance for our undecidability results. This principle is obviously semantically valid, since for any $e \in E$, we have $e = e \circ e$ and thus if $e \models_{e} A$ then $e \models_{e} A * A$.

However, it is far from obvious that it is provable in BBI, and still less so in Minimal BBI. The broad idea of the BBI proof is as follows. First, from $I \land A$ we can deduce $((I \land A) * I)$ and thus $(I \land A) * (I \land (A \lor \neg A))$ using the usual law of excluded middle in classical logic. Since \lor distributes over both \land and *, the latter sequent yields $((I \land A) * (I \land A)) \lor ((I \land A) * (I \land \neg A))$ but $(I \land A) * (I \land \neg A)$ implies $A \land \neg A$, which is inconsistent.

In Minimal BBI, the situation is complicated further by the absence of \neg in the language, forcing us to use Peirce's law, in the shape of the rule (EM). The following lemma spells out the full details.

LEMMA 6.4. The restricted *-contraction, given by a sequent of the form

$$\mathbf{I} \wedge \mathbf{A} \vdash \mathbf{A} \ast \mathbf{A} \tag{11}$$

is provable in Minimal BBI.

PROOF. We make free use of the derived rules of Minimal BBI given by Proposition 6.3. According to the reversible version of the rule (I), the sequent (11) follows from

$$\mathbf{I} \vdash (\mathbf{I} \land A) \twoheadrightarrow (A \ast A),$$

which is notation for the formula

$$\mathbf{I} \to ((\mathbf{I} \land A) \twoheadrightarrow (A \ast A)). \tag{12}$$

Using the "excluded middle" rule (EM) in Proposition 6.3, we can derive the formula (12) from the following two sequents:

$$A \vdash \mathbf{I} \to ((\mathbf{I} \land A) \twoheadrightarrow (A \ast A)) \tag{13}$$

and

 $A \to (A * A) \vdash I \to ((I \land A) \twoheadrightarrow (A * A)).$ (14)

We proceed by demonstrating how to derive each of (13) and (14).

—We derive the sequent (13) as follows. First, using the fact that $I \land A \vdash A(axiom (\beta_6))$ and the rule (α_6) for * we have:

$$(\mathbf{I} \wedge A) * (\mathbf{I} \wedge A) \vdash A * (\mathbf{I} \wedge A).$$

By a similar sequence of reasoning, but additionally using commutativity of $*(\alpha_1)$, we have $A * (I \land A) \vdash A * A$, whereby we have by (Tr)

$$(\mathbf{I} \wedge A) * (\mathbf{I} \wedge A) \vdash A * A.$$

Using the derived rule (-*), we obtain:

$$[\land A \vdash ((I \land A) \twoheadrightarrow (A \ast A))]$$

and, by means of the derived rule (\rightarrow) , we conclude with the desired sequent (13).

—We derive the sequent (14) in the following way. First, using \wedge -weakening (β_5), (β_6) and the axiom (α_4) for I, we can derive each of the following:

$$(\mathbf{I} \land (A \to (A * A))) * (\mathbf{I} \land A) \vdash \mathbf{I} * (\mathbf{I} \land A)$$

and

$$\mathbf{I} * (\mathbf{I} \land A) \vdash A$$
,

whence by transitivity (Tr) we obtain:

$$(\mathbf{I} \land (A \to (A * A))) * (\mathbf{I} \land A) \vdash A.$$
(15)

Next, using the same principles, we can derive

$$(\mathbf{I} \land (A \to (A * A))) * (\mathbf{I} \land A) \vdash (\mathbf{I} \land (A \to (A * A))) * \mathbf{I},$$

and

$$(\mathbf{I} \land (A \to (A * A))) * \mathbf{I} \vdash (A \to (A * A)),$$

resulting by transitivity (Tr) in

$$(\mathbf{I} \land (A \to (A * A))) * (\mathbf{I} \land A) \vdash (A \to (A * A)).$$
(16)

Using the axiom (β_2) from Figure 2 and the derived rules (\wedge), (\rightarrow) and (Tr), it is straightforward to derive from (15) and (16):

$$(\mathbf{I} \land (A \to (A * A))) * (\mathbf{I} \land A) \vdash A * A.$$

Hence, by applying the derived rules (-*), we obtain

$$\mathbf{I} \land (A \rightarrow (A \ast A)) \vdash ((\mathbf{I} \land A) \twoheadrightarrow (A \ast A))$$

and, by means of the derived rules (\rightarrow) , we conclude with the desired sequent (14). \Box

The proof principles of Proposition 6.3 and Lemma 6.4 are the main ones that are needed for correctness of our encoding of Minsky machines in the next section.

7. ENCODING MINSKY MACHINE COMPUTATIONS IN MINIMAL BBI

In this section, we give our encoding of terminating computations of (nondeterministic) two-counter Minsky machines as provable sequents of Minimal BBI. That is to say, given a Minsky machine M and initial configuration C our aim is to give a sequent $\mathcal{F}_{M,C}$ such that M terminates from C just in case $\mathcal{F}_{M,C}$ is provable in Minimal BBI (as per the strategy in Section 5). First, we explain how $\mathcal{F}_{M,C}$ is constructed from M and C, and then in Section 7.1 we develop some intuition for our choice of encoding.

Definition 7.1. A nondeterministic, two-counter Minsky machine M [Minsky 1967] with non-negative counters c_1, c_2 is given by a finite set of labelled *instructions* of the form:

"increment
$$c_k$$
 by 1" $L_i: c_k + +;$ goto $L_j;$ "decrement c_k by 1" $L_i: c_k - -;$ goto $L_j;$ "zero-test on c_k " $L_i:$ if $c_k = 0$ goto $L_j;$ "goto" $L_i:$ goto $L_j;$

where $k \in \{1, 2\}, i \ge 1$ and $j \ge 0$.

$$\begin{array}{ll} (L_i:c_1++;\operatorname{\textbf{goto}}\ L_j;) \in M & (L_i:c_2++;\operatorname{\textbf{goto}}\ L_j;) \in M \\ \hline \langle L_i,n_1,n_2 \rangle \rightsquigarrow_M \langle L_j,n_1+1,n_2 \rangle & \langle L_i,n_1,n_2 \rangle \sim_M \langle L_j,n_1,n_2+1 \rangle \\ \hline (L_i:c_1--;\operatorname{\textbf{goto}}\ L_j;) \in M & (L_i:c_2--;\operatorname{\textbf{goto}}\ L_j;) \in M \\ \hline \langle L_i,n_1+1,n_2 \rangle \rightsquigarrow_M \langle L_j,n_1,n_2 \rangle & (L_i:c_2--;\operatorname{\textbf{goto}}\ L_j;) \in M \\ \hline \langle L_i,n_1,n_2+1 \rangle \rightsquigarrow_M \langle L_j,n_1,n_2 \rangle \\ \hline (L_i:\operatorname{\textbf{if}}\ c_1=0 \operatorname{\textbf{goto}}\ L_j;) \in M & (L_i:\operatorname{\textbf{if}}\ c_2=0 \operatorname{\textbf{goto}}\ L_j;) \in M \\ \hline \langle L_i,n_1,0 \rangle \rightsquigarrow_M \langle L_j,n_1,0 \rangle & (L_i:\operatorname{\textbf{goto}}\ L_j;) \in M \\ \hline \langle L_i,n_1,n_2 \rangle \sim_M \langle L_j,n_1,0 \rangle \\ \hline \end{array}$$

Fig. 3. One-step semantics of two-counter Minsky machines.

Nondeterminism of M means that each "state label" L_i may have multiple associated instructions. The labels L_0 and L_1 are reserved for the *final* and *initial* states of M, respectively. In particular, L_0 may not label any instructions.

To cope more easily with zero-test instructions, we also add the special labels L_{-1} and L_{-2} which come equipped with the following four instructions (and which may not label any other instructions).

$$L_{-1}: c_2 - ; \text{goto } L_{-1}; \quad L_{-1}: \text{goto } L_0; \\ L_{-2}: c_1 - ; \text{goto } L_{-2}; \quad L_{-2}: \text{goto } L_0;$$
(18)

A *configuration* of *M* is given by (L, n_1, n_2) , where the label *L* is the current state of *M*, and n_1 and n_2 are the current values of counters c_1 and c_2 , respectively.

We write \rightsquigarrow_M for the one-step relation between configurations of M; the one-step semantics of Minsky machines is given by Figure 3. We let \rightsquigarrow_M^* be the reflexive-transitive closure of \rightsquigarrow_M , so that $\langle L, n_1, n_2 \rangle \rightsquigarrow_M^* \langle L', n'_1, n'_2 \rangle$ if M can go from $\langle L, n_1, n_2 \rangle$ to $\langle L', n'_1, n'_2 \rangle$ in a finite number of steps. If $\langle L, n_1, n_2 \rangle \rightsquigarrow_M^* \langle L_0, 0, 0 \rangle$, we say that M terminates from $\langle L, n_1, n_2 \rangle$, written $\langle L, n_1, n_2 \rangle \Downarrow_M$.

The specific role of the special labels L_{-1} and L_{-2} is explained by the following lemma.

LEMMA 7.2. $(L_{-k}, n_1, n_2) \Downarrow_M$ if and only if $n_k = 0$, where $k \in \{1, 2\}$.

PROOF. Formally, the proof proceeds by induction on n_2 if k = 1, and vice versa; we just provide a sketch here since the details are straightforward. For the "if" direction, we simply apply the relevant instructions from the group (18). For the "only if" direction, we simply notice that, by construction, no other instructions except those in the group (18) are applicable to any configuration of the form $\langle L_{-k}, n_1, n_2 \rangle$. \Box

Definition 7.3. In our encoding, we use the following abbreviation. We fix an atomic proposition *b*, and henceforth define a "relative negation" by: $-A =_{def} (A \rightarrow b)$.

Our relative negation, defined as multiplicative implication into a constant, can be seen as a natural multiplicative analogue of standard intuitionistic negation, which is defined by $\neg A = A \rightarrow \bot$. We derive some useful properties of relative negation in Lemma 8.1.

Definition 7.4 (*Machine Encoding*). For any instruction γ from Definition 7.1, we define the formula $\kappa(\gamma)$ as follows:

$$\begin{split} \kappa(L_i:c_k++; \textbf{goto } L_j;) &=_{def} (-(l_j * p_k) - * - l_i) \\ \kappa(L_i:c_k--; \textbf{goto } L_j;) &=_{def} (-l_j - * - (l_i * p_k)) \\ \kappa(L_i: \textbf{if } c_k = 0 \textbf{ goto } L_j;) &=_{def} (-(l_j \vee l_{-k}) - * - l_i) \\ \kappa(L_i: \textbf{goto } L_j;) &=_{def} (-l_j - * - l_i), \end{split}$$

where p_1 , p_2 , l_{-2} , l_{-1} , l_0 , l_1 , l_2 , ... are distinct atomic propositions (p_1 and p_2 are used to represent the counters c_1 and c_2 , respectively).

Recall that, by Definition 6.2, the formula $(-(l_j \lor l_{-k}) \twoheadrightarrow -l_i)$ abbreviates the formula $(-((l_{-k} \to l_j) \to l_j) \twoheadrightarrow -l_i)$.

Then, for a Minsky machine M given by instructions $\{\gamma_1, \gamma_2, \ldots, \gamma_t\}$, we define its encoding formula $\kappa(M)$ by

$$\kappa(M) =_{\mathrm{def}} \mathrm{I} \wedge \bigwedge_{i=1}^t \kappa(\gamma_i).$$

Definition 7.5 (*Encoding of Terminating Configurations*). We will encode nonnegative integers *n*, the contents of a Minsky machine counter, as a formula of the form

$$p^n =_{\text{def}} \underbrace{p * p * \cdots * p}_{n \text{ times}},$$

with $p^0 =_{def} I$.

Accordingly, we encode a machine configuration of the form

$$C = \langle L_i, n_1, n_2 \rangle$$

as a *-conjunction of the propositional variable l_i with n_1 copies of p_1 and n_2 copies of p_2 :

$$l_i * p_1^{n_1} * p_2^{n_2}.$$

The fact that $\langle L_0, 0, 0 \rangle$ is a terminating configuration is encoded by the following formula:

$$\mathbf{I} \wedge -l_0$$
.

Putting everything together, termination of M from $\langle L_i, n_1, n_2 \rangle$ will be encoded by the following sequent $\mathcal{F}_{M,C}$:

$$\mathcal{F}_{M,C} =_{\scriptscriptstyle \mathrm{def}} \kappa(M) \ast l_i \ast p_1^{n_1} \ast p_2^{n_2} \ast (\mathrm{I} \land -l_0) \vdash b,$$

where $\kappa(M)$ is the machine encoding given by Definition 7.4 and *b* is the fixed proposition letter used in our "relative negation" (Definition 7.3).

7.1. Intuition for Our Encoding

In accordance with our proof strategy in Section 5, our encoding is intended to achieve two complementary goals.

(1) On one hand, we have to show provability (in Minimal BBI) of $\mathcal{F}_{M,C}$ whenever M terminates from C. We construct the proof of $\mathcal{F}_{M,C}$ by induction on the length m of the terminating computation, using as subproofs the proofs given by induction for terminating computations of shorter length. We give the full details of this construction in Section 8.

(2) On the other hand, for a fixed memory model from Section 2, we have to find a valuation ρ such that M terminates from C of the form $\langle L_i, n_1, n_2 \rangle$ whenever $\mathcal{F}_{M,C}$ is valid under this valuation ρ , that is, whenever

$$[\![\kappa(M) * l_i * p_1^{n_1} * p_2^{n_2} * (\mathbf{I} \wedge -l_0)]\!]_{\rho} \subseteq \rho(b).$$

To obtain the required termination of M from C from this inclusion, it stands to reason to define $\rho(b)$ so as to represent all terminating configurations, and then to show that

$$e \in \llbracket \kappa(M) \rrbracket_{\rho}$$
 and $e \in \llbracket I \land -l_0 \rrbracket_{\rho}$,

where *e* is a unit of the memory model, resulting in the inclusion:

$$[[l_i * p_1^{n_1} * p_2^{n_2}]]_{\rho} \subseteq \rho(b).$$

Provided that each element of $[l_i * p_1^{n_1} * p_2^{n_2}]_{\rho}$ uniquely determines the configuration $\langle L_i, n_1, n_2 \rangle$ (cf. Lemma 9.2), we can then deduce that $\langle L_i, n_1, n_2 \rangle \downarrow_M$.

However, an additional twist to the problem is that we need a rather complicated valuation ρ in the memory models of Section 2, because of the way the *partial* composition is defined in these models. We look at this point in more detail in Sections 9.2 and 10.

We note that a direct adaptation of the encoding of Minsky machines developed for full linear logic in Kanovich [1995] does not work properly for separation logic due to the differences between linear logic and separation logic (discussed further in Section 12).

Roughly speaking, in the encoding of Kanovich [1995], each step in the derivation of the "encoding sequent" corresponds to a single *forward step* from C to C' within the computation of machine M (which is not necessarily terminating).

In contrast, in our encoding, each step in the derivation corresponds to a "backward move" from the class of all terminating computations starting from C' to the class of longer terminating computations starting from C.

We illustrate this point in more detail.

Given a memory model, suppose that a valuation ρ is chosen such that each element of $[l_i * p_1^{n_1} * p_2^{n_2}]_{\rho}$ uniquely determines the configuration $\langle L_i, n_1, n_2 \rangle$ (cf. Lemma 9.2).

As discussed previously, to guarantee the faithfulness of our encoding, we need to check that for such a valuation ρ , the encoding guarantees that $e \in [\![\kappa(M)]\!]_{\rho}$, that is, for each of the machine instruction γ we can provide $e \in [\![\kappa(\gamma)]\!]_{\rho}$.

For any instruction γ , the formula $\kappa(\gamma)$ is of the form $(-A \twoheadrightarrow -B)$ where A is of the form l_j , $(l_j \lor l_{-k})$ or $(l_j * p_k)$, and B is of the form l_i or $(l_i * p_k)$. Thus, recalling that $-A =_{def} (A \twoheadrightarrow b)$, and $-B =_{def} (B \twoheadrightarrow b)$, the statement $e \in [\kappa(\gamma)]_{\rho}$ is equivalent to the inclusion

$$\llbracket A \twoheadrightarrow b \rrbracket_{\rho} \subseteq \llbracket B \twoheadrightarrow b \rrbracket_{\rho}.$$

Since, by Lemma 3.8, the statement $d \in [\![A \twoheadrightarrow b]\!]_{\rho}$ means that $[\![A]\!]_{\rho} \cdot \{d\} \subseteq \rho(b)$, this inclusion can be rewritten as the rule that for all d,

$$\frac{\llbracket A \rrbracket_{\rho} \cdot \{d\} \subseteq \rho(b)}{\llbracket B \rrbracket_{\rho} \cdot \{d\} \subseteq \rho(b)}.$$
(19)

For instance, in the case of the increment instruction

$$L_i: c_1 + +; \mathbf{goto} \ L_j;, \tag{20}$$

we must show that the following rule is correct for any *d*:

$$\frac{\llbracket l_j * p_1 \rrbracket_{\rho} \cdot \{d\} \subseteq \rho(b)}{\llbracket l_i \rrbracket_{\rho} \cdot \{d\} \subseteq \rho(b)}.$$

Our choice of valuation (cf. Lemma 9.2) ensures that if $[l_j * p_1]_{\rho} \cdot \{d\} \subseteq \rho(b)$, then d must belong to a set of the form $[p_1^{n_1} * p_2^{n_2}]_{\rho}$, so that this rule becomes

$$\frac{\llbracket l_j * p_1^{n_1+1} * p_2^{n_2} \rrbracket_{\rho} \subseteq \rho(b)}{\llbracket l_i * p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho} \subseteq \rho(b)}$$

or, paraphrasing,

"*M* terminates from the configuration
$$\langle L_j, n_1 + 1, n_2 \rangle$$
",
"*M* terminates from the configuration $\langle L_i, n_1, n_2 \rangle$ ",

which is a correct statement according to the increment instruction (20) at hand. Other instructions are treated similarly.

8. FROM COMPUTATIONS TO MINIMAL BBI PROOFS

Here, we show in detail that the sequent $\mathcal{F}_{M,C}$, defined in the previous section, is provable in Minimal BBI whenever M terminates on C. The converse direction will be established in Section 9.

First, the following lemma derives useful properties of -A which illustrate its behaviour as a multiplicative analogue of intuitionistic negation, and will be essential to the proof of our main result.

LEMMA 8.1. The following sequents and proof rules are derivable in Minimal BBI.

- (a) $A \vdash --A$
- $(b) ---A \vdash -A$
- $(c) A * (-B - A) \vdash - B$

$$(d) \quad \frac{A * B \vdash C}{A * - - B \vdash - - C}$$

(e) $\frac{A * B \vdash D}{A * - -(B \lor C) \vdash - -D}$

PROOF. We derive each sequent or proof rule directly in Minimal BBI, making use of the derived rules given by Proposition 6.3.

- (a) According to the Minimal BBI axiom (α_3) , we have $A * (A \twoheadrightarrow b) \vdash b$ provable. Thus, by applying the derived rule $(\neg *)$, we obtain $A \vdash ((A \twoheadrightarrow b) \twoheadrightarrow b)$, that is, $A \vdash \neg \neg A$, as required.
- (b) According to the Minimal BBI axiom (α₃), we have --A*(--A→ b) ⊢ b provable. Also, A⊢ --A is provable by part (a). Thus, by the derived rule (Tr), we obtain A*(--A→ b) ⊢ b. By applying (→) again, we obtain (--A→ b) ⊢ A→ b, i.e. ---A⊢ -A, as required.
- (c) We have $-B * (-B A) \vdash -A$ an instance of the Minimal BBI axiom (α_3), which can then be rewritten as $-B * (-B A) \vdash A b$. By applying (-*), we obtain $A * (-B A) \vdash -B b$, that is, $A * (-B A) \vdash -B$, as required.
- (d) We have $A * B \vdash C$ by assumption and $C \vdash --C$ by part (a), whence by (Tr) we obtain $A * B \vdash --C$. By applying (-*), we obtain $A * -C \vdash -B$. Since $-B \vdash ---B$ is derivable by part (a), we obtain $A * -C \vdash ---B$ by (Tr). By applying (-*) again, this can be transformed to the required $A * -B \vdash --C$.
- (e) By applying (→) to the premises A * B ⊢ D and A * C ⊢ D, we have B ⊢ (A → D) and C ⊢ (A → D). Thus, by applying the derived rule (∨), we obtain B ∨ C ⊢ (A → D). Applying (→), we get A * (B ∨ C) ⊢ D. Finally, we apply the derived rule given by part (d) to obtain A * --(B ∨ C) ⊢ --D as required. □

In the process of computation, each instruction of a Minsky machine can be reused an unlimited number of times. In order for us to simulate Minsky computations within Minimal BBI proofs, it is essential that the formulas $\kappa(\gamma)$ representing reusable instructions can be duplicated as needed, which follows from the restricted *-contraction given by Lemma 6.4.

LEMMA 8.2. For each instruction γ of a machine M, the sequent

$$\kappa(M) \vdash \kappa(M) * \kappa(\gamma)$$

is derivable in Minimal BBI.

PROOF. Writing $M = \{\gamma_1, \gamma_2, \dots, \gamma_t\}$, we have $\kappa(M) = (I \land \bigwedge_{i=1}^t \kappa(\gamma_i))$ and $\gamma = \gamma_j$ for some $1 \le j \le t$. First, using the derived rules (Id) and (\land) and the axiom (β_5) for \land , we can derive

$$\kappa(M) \vdash \mathbf{I} \wedge \kappa(M)$$

Next, we have as an instance of restricted *-contraction (Lemma 6.4)

$$\mathbf{I} \wedge \kappa(M) \vdash \kappa(M) * \kappa(M).$$

We have $\kappa(M) \vdash \kappa(\gamma_j)$ derivable in Minimal BBI by using weakening for \wedge (given by the axioms (β_5) and (β_6)) and the derived transitivity rule (Tr) of Proposition 6.3. Thus, by applying the rule (α_6) , we obtain

$$\kappa(M) \ast \kappa(M) \vdash \kappa(M) \ast \kappa(\gamma_i).$$

Thus, using the transitivity rule (Tr), we obtain $\kappa(M) \vdash \kappa(M) * \kappa(\gamma_j)$ as required. \Box

THEOREM 8.3. Let M be a Minsky machine, and for a configuration C of the form $\langle L_i, n_1, n_2 \rangle$, suppose that M terminates from C. Then, the following sequent $\mathcal{F}_{M,C}$ is derivable in Minimal BBI:

$$\kappa(M) * l_i * p_1^{n_1} * p_2^{n_2} * (\mathbf{I} \wedge -l_0) \vdash b.$$
(21)

PROOF. We make free use of the derived rules of Minimal BBI given by Proposition 6.3. First, we show that it suffices to derive the sequent:

$$\kappa(M) * l_i * p_1^{n_1} * p_2^{n_2} \vdash --l_0.$$
(22)

To see this, suppose we have $A \vdash --l_0$, whence by applying the derived rule (-*), we obtain $-l_0 \vdash (A \twoheadrightarrow b)$. Since $I \land -l_0 \vdash -l_0$ is an instance of the axiom (β_6), we obtain $I \land -l_0 \vdash (A \twoheadrightarrow b)$ by applying the derived rule (Tr). By applying (-*) again, we obtain $A * (I \land -l_0) \vdash b$ as required.

We show that (22) is derivable in Minimal BBI by induction on the length m of the computation of $\langle L_i, n_1, n_2 \rangle \sim_M^* \langle L_0, 0, 0 \rangle$. In the base case m = 0, we have $n_1 = n_2 = 0$, and must derive:

$$\kappa(M) * l_0 * \mathbf{I} * \mathbf{I} \vdash \mathbf{--}l_0.$$

This is easily derivable using the equivalence $I * A \equiv A$, weakening for \land and part (a) of Lemma 8.1.

Next, we assume that the result holds for all computations of length m - 1, and show that it holds for any computation of length m. We then proceed by case distinction on the instruction γ which yields the first step of the computation. We show the cases for a goto instruction, and for increment, decrement and zero-test instructions with the counter variable k = 1; the cases for k = 2 are similar.

Case $\gamma = (L_i: goto \ L_j;)$. By the case assumption, we have $\langle L_i, n_1, n_2 \rangle \rightsquigarrow_M \langle L_j, n_1, n_2 \rangle$, and we are required to show that the following sequent is derivable:

$$\kappa(M) * l_i * p_1^{n_1} * p_2^{n_2} \vdash --l_0.$$

J. Brotherston and M. Kanovich

By the induction hypothesis, we can derive

$$(M) * l_j * p_1^{n_1} * p_2^{n_2} \vdash --l_0.$$

By applying part (d) of Lemma 8.1, we obtain

$$k(M) * - l_j * p_1^{n_1} * p_2^{n_2} \vdash - - - l_0.$$

Since $---l_0 \vdash --l_0$ is derivable by part (b) of Lemma 8.1, we obtain by (Tr)

$$\kappa(M) * - -l_j * p_1^{n_1} * p_2^{n_2} \vdash - -l_0.$$

Now since $(-l_j - -l_i) * l_i \vdash - l_j$ is provable by part (c) of Lemma 8.1, we obtain by (Tr) and the derived rule (-*)

$$\kappa(M) * (-l_j \twoheadrightarrow -l_i) * l_i * p_1^{n_1} * p_2^{n_2} \vdash --l_0.$$

Since $\gamma \in M$ and $\kappa(\gamma) = (-l_j \twoheadrightarrow -l_i)$, we have $\kappa(M) \vdash \kappa(M) \ast (-l_j \twoheadrightarrow -l_i)$ provable by Lemma 8.2. Thus, we derive by (Tr) and (-*):

$$c(M) * l_i * p_1^{n_1} * p_2^{n_2} \vdash --l_0,$$

which completes the case.

Case $\gamma = (L_i: c_1 + +; goto L_j;)$. By the case assumption, we have $\langle L_i, n_1, n_2 \rangle \sim_M \langle L_j, n_1 + 1, n_2 \rangle$, and we are required to show that the following sequent is derivable:

$$\kappa(M)*l_i*p_1^{n_1}*p_2^{n_2}\vdash --l_0.$$

By the induction hypothesis, we can derive

$$\kappa(M) * l_j * p_1^{n_1+1} * p_2^{n_2} \vdash --l_0.$$

By applying part (d) of Lemma 8.1, we obtain

$$\kappa(M) * - (l_j * p_1) * p_1^{n_1} * p_2^{n_2} \vdash - - - l_0.$$

Since $---l_0 \vdash --l_0$ is derivable by part (b) of Lemma 8.1, we obtain by (Tr)

$$x(M) * - -(l_j * p_1) * p_1^{n_1} * p_2^{n_2} \vdash - -l_0.$$

Now since $(-(l_j * p_1) - - l_i) * l_i \vdash - -(l_j * p_1)$ is provable by part (c) of Lemma 8.1, we obtain by (Tr) and (-*)

$$\kappa(M) * (-(l_j * p_1) - - l_i) * l_i * p_1^{n_1} * p_2^{n_2} \vdash - -l_0.$$

As $\gamma \in M$ and $\kappa(\gamma) = (-(l_j * p_1) - - l_i)$, we have $\kappa(M) \vdash \kappa(M) * (-(l_j * p_1) - - l_i)$ provable by Lemma 8.2. Thus, we derive by (Tr) and (-*)

$$\kappa(M) * l_i * p_1^{n_1} * p_2^{n_2} \vdash --l_0,$$

which completes the case.

Case $\gamma = (L_i: c_1 - -; goto L_j;)$. By the case assumption, we have $\langle L_i, n_1 + 1, n_2 \rangle \rightsquigarrow_M \langle L_j, n_1, n_2 \rangle$, and we are required to show that the following sequent is derivable:

$$\kappa(M) * l_i * p_1^{n_1+1} * p_2^{n_2} \vdash --l_0$$

By the induction hypothesis, we can derive

$$\kappa(M)*l_j*p_1^{n_1}*p_2^{n_2}\vdash --l_0.$$

Using parts (b), (c), and (d) of Lemma 8.1 together with (Tr) and (-*) in a similar way to previous cases, we obtain

$$\kappa(M) * (-l_j - (l_i * p_1)) * l_i * p_1^{n_1+1} * p_2^{n_2} \vdash - -l_0.$$

Since $\gamma \in M$ and $\kappa(\gamma) = (-l_j \twoheadrightarrow -(l_i * p_1))$, we have $\kappa(M) \vdash \kappa(M) * (-l_j \twoheadrightarrow -(l_i * p_1))$ provable by Lemma 8.2. Thus, we derive by (Tr) and (-*), as required:

$$\kappa(M) * l_i * p_1^{n_1+1} * p_2^{n_2} \vdash --l_0.$$

Case $\gamma = (L_i: if c_1 = 0 \text{ goto } L_j;)$. By the case assumption, we have $\langle L_i, 0, n_2 \rangle \rightsquigarrow_M \langle L_j, 0, n_2 \rangle$, and must derive the following sequent:

$$\kappa(M) * l_i * \mathbf{I} * p_2^{n_2} \vdash --l_0$$

First, by the induction hypothesis, we can derive

$$\kappa(M) * l_j * \mathbf{I} * p_2^{n_2} \vdash --l_0.$$
⁽²³⁾

Next, note that by Lemma 7.2, we have $\langle L_{-1}, 0, n_2 \rangle \Downarrow_M$. Since the computation of $\langle L_{-1}, 0, n_2 \rangle \rightsquigarrow_M^* \langle L_0, 0, 0 \rangle$ involves only decrement and goto instructions (see group (18) in Definition 7.1) by construction, the cases already considered above are sufficient to establish the present theorem for the configuration $\langle L_{-1}, 0, n_2 \rangle$. Thus, we can also derive

$$\kappa(M) * l_{-1} * \mathbf{I} * p_2^{n_2} \vdash --l_0.$$
(24)

Thus, by applying part (e) of Lemma 8.1, we obtain from (23) and (24)

$$\kappa(M) \ast - -(l_j \lor l_{-1}) \ast \mathrm{I} \ast p_2^{n_2} \vdash - - - - l_0.$$

Since $---l_0 \vdash --l_0$ is derivable by part (b) of Lemma 8.1, we obtain by (Tr)

$$\kappa(M) \ast - -(l_j \lor l_{-1}) \ast \mathrm{I} \ast p_2^{n_2} \vdash - -l_0.$$

Then, as $(-(l_j \vee l_{-1}) \twoheadrightarrow -l_i) * l_i \vdash --(l_j \vee l_{-1})$ is provable by part (c) of Lemma 8.1, we obtain by (Tr) and (-*)

$$\kappa(M) \ast (-(l_j \lor l_{-1}) \twoheadrightarrow -l_i) \ast \mathbf{I} \ast l_i \ast p_2^{n_2} \vdash --l_0.$$

Since $\gamma \in M$ and $\kappa(\gamma) = (-(l_j \vee l_{-1}) \twoheadrightarrow -l_i)$, we have $\kappa(M) \vdash \kappa(M) * (-(l_j \vee l_{-1}) \twoheadrightarrow -l_i)$ provable by Lemma 8.2. Thus, we derive by (Tr) and (-*)

$$\kappa(M) * l_i * \mathbf{I} * p_2^{n_2} \vdash --l_0,$$

which completes the case, and the proof. \Box

9. FROM VALIDITY TO TERMINATING COMPUTATIONS

In this section, our goal is to show that for each of the concrete models given in Section 2, we have $\langle L_i, n_1, n_2 \rangle \Downarrow_M$ whenever the following sequent $\mathcal{F}_{M, \langle L_i, n_1, n_2 \rangle}$ is valid in this particular model

$$\kappa(M) * l_i * p_1^{n_1} * p_2^{n_2} * (\mathbf{I} \wedge -l_0) \vdash b$$

For the sake of perspicuity, we establish this property first for the simplest such model, the *RAM-domain model* from Section 2.5.

Then, we show how to extend our approach to any of the memory models from Section 2.

In particular, we extend our approach to the most general stack-and-heap models from Section 2.4, of which all the models in Sections 2.1–2.5 can be seen as special instances (see Remark 2.1).

Notice that, to provide undecidability, the set of *locations* L must be infinite (cf. Sections 9.2 and 10).

The RAM-domain model case also suffices to cover the Petri net models from Section 2.7.

As for the finite multiset models of Section 2.6, the (un)desired undecidability property can be established even in the case of the multisets over a fixed *finite* set L (see Section 9.5).

9.1. Valuation for the RAM-Domain Model

Definition 9.1. Given a machine M, we introduce the following valuation ρ_0 for the RAM-domain model $(\mathcal{D}, \circ, \{e_0\})$ of Section 2.5:

where $i \geq -2$, and

$$ho_0(b) = igcup_{\langle L_i, n_1, n_2
angle \downarrow_M} \llbracket l_i * p_1^{n_1} * p_2^{n_2}
rbrack_{
ho_0}$$

where *b* is the distinguished propositional variable introduced in Definition 7.3. (The reason behind our choice for $\rho_0(b)$ is given in Section 7.1.)

LEMMA 9.2. For any $d \in D$, $n \in \mathbb{N}$ and $k \in \{1, 2\}$, Definition 9.1 guarantees that $d \in [\![p_k^n]\!]_{\rho_0}$ if and only if d consists of exactly n distinct numbers of the form $2^k \cdot (2m+1)$ (where $m \ge 1$).

Thus, $\llbracket l_i * p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_0}$ is not empty, and each of the elements of $\llbracket l_i * p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_0}$ uniquely determines the configuration $\langle L_i, n_1, n_2 \rangle$.

PROOF. The first part is by induction on *n*. In the case n = 0, we have $[\![p_k^0]\!]_{\rho_0} = [\![I]\!]_{\rho_0} = [\![e_0]\!]_{\rho_0}$, where e_0 is \emptyset . Thus, $d \in [\![p_k^0]\!]_{\rho_0}$ iff $d = \emptyset$ iff *d* consists of zero numbers of the form $2^k \cdot (2m+1)$.

In the case n > 0, we have, using Lemma 3.8:

$$egin{aligned} & \llbracket p_k^n
rbrace_{
ho_0} & = \ \llbracket p_k * p_k^{n-1}
rbrace_{
ho_0} \ & = \ \llbracket p_k
rbrace_{
ho_0} \cdot \llbracket p_k^{n-1}
rbrace_{
ho_0} \ & = \ \{d' \circ d'' \mid d' \in
ho_0(p_k), d'' \in \llbracket p_k^{n-1}
rbrace_{
ho_0}\}. \end{aligned}$$

Thus, $d \in [\![p_k^n]\!]_{\rho_0}$ iff it is the union of disjoint sets d' and d'' with $d' \in \rho_0(p_k)$ and $d'' \in [\![p_k^{n-1}]\!]_{\rho_0}$. By induction hypothesis, $d'' \in [\![p_k^{n-1}]\!]_{\rho_0}$ iff d'' consists of exactly n-1 distinct numbers of the form $2^k \cdot (2m+1)$, and by construction it holds that $d' \in \rho_0(p_k)$ iff $d' = \{2^k \cdot (2m'+1)\}$ for some m'. Since d' and d'' must be disjoint, we have $d \in [\![p_k^n]\!]_{\rho_0}$ iff d consists of exactly n numbers of the form $2^k \cdot (2m+1)$, as required.

For the second part of the lemma, we have, using Lemma 3.8:

$$egin{aligned} & \llbracket l_i * p_1^{n_1} * p_2^{n_2}
rbrace_{
ho_0} & = \ \llbracket l_i
rbrace_{
ho_0} \cdot \llbracket p_1^{n_1}
rbrace_{
ho_0} \cdot \llbracket p_2^{n_2}
rbrace_{
ho_0} \ & = \ \{ d_1 \circ d_2 \circ d_3 \mid d_1 \in
ho_0(l_i), d_2 \in \llbracket p_1^{n_1}
rbrace_{
ho_0}, d_3 \in \llbracket p_2^{n_2}
rbrace_{
ho_0} \}. \end{aligned}$$

Thus, $d \in \llbracket l_i * p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_0}$ iff it is the union of disjoint sets d_1, d_2 and d_3 with $d_1 \in \rho_0(l_i)$, $d_2 \in \llbracket p_1^{n_1} \rrbracket_{\rho_0}$ and $d_3 \in \llbracket p_2^{n_2} \rrbracket_{\rho_0}$. By the first part of the lemma, d_2 and d_3 consist of n_1 distinct numbers of form 2(2m + 1) and n_2 distinct numbers of the form 4(2m + 1), respectively, whereas by construction $d_1 = \{2^{i+5} \cdot (2m'+1)\}$ for some $m' \ge 1$ and $i \ge -2$.

To see that the decomposition of d into $d_1 \circ d_2 \circ d_3$ exists and is unique, we must show that d_1, d_2, d_3 are nonoverlapping. To see this, suppose that $2^i \cdot (2m + 1) = 2^j \cdot (2m' + 1)$ where $i \neq j$, and assume without loss of generality that j > i. Then, by simple manipulation, we have $2m = 2^{j-i+1}m' + 2^{j-i} - 1$, but then 2m is even while $2^{j-i+1}m' + 2^{j-i} - 1$ is odd, contradiction. Thus, $[l_i * p_1^{n_1} * p_2^{n_2}]_{\rho_0}$ is not empty, and each of its elements uniquely determines L_i, n_1 and n_2 , and hence the configuration $\langle L_i, n_1, n_2 \rangle$. \Box

9.2. Do We Need Infinite Valuations?

Our choice of $\rho_0(p_1)$ and $\rho_0(p_2)$ to have infinitely many disjoint elements is dictated by peculiarities of composition \circ in the heap model. Moreover, for any finite choice of $\rho_0(p_k)$, we can show that for all sufficiently large *n*,

$$\llbracket p_k^n \rrbracket_{\rho_0} = \emptyset,$$

which obstructs us in uniquely representing the contents n of the Minsky machine counter c_k by the formula p_k^n . We discuss the impact upon decidability of a restriction to finite valuations in Section 10.

9.3. Formal Details

Now we prove the basic lemma.

LEMMA 9.3. $e_0 \models_{\rho_0} \kappa(M)$ for any machine M.

PROOF. Writing $M = \{\gamma_1, \ldots, \gamma_t\}$, we have by Definition 3.7:

$$e_{0} \models_{\rho_{0}} \kappa(M) \Leftrightarrow e_{0} \models_{\rho_{0}} \mathbf{I} \land \bigwedge_{i=1}^{t} \kappa(\gamma_{i})$$

$$\Leftrightarrow e_{0} \in \{e_{0}\} \text{ and } \forall i \in \{1, \ldots, t\}. e_{0} \models_{\rho_{0}} \kappa(\gamma_{i})$$

Thus, it suffices to show that $e_0 \models_{\rho_0} \kappa(\gamma)$ for any instruction γ . Recalling that $-A =_{def} (A \twoheadrightarrow b)$, we shall make use of the fact that, for any $d \in \mathcal{D}$ and any formula A,

$$d \models_{\rho_0} - A \Leftrightarrow \forall d'. (d, d' \text{ disjoint and } d' \models_{\rho_0} A) \text{ implies } d \circ d' \in \rho_0(b).$$
 (25)

We present the cases for a goto instruction, and for increment, decrement and zero-test instructions with counter variable k = 1; the cases where k = 2 are similar.

Case $\gamma = (L_i: goto L_j;)$. We have $\kappa(\gamma) = (-l_j \twoheadrightarrow -l_i)$, so must show $e_0 \models_{\rho_0} -l_j \twoheadrightarrow -l_i$. Using the fact that $e_0 \circ d = d$, this amounts to showing, for any $d \in \mathcal{D}$,

$$d \models_{\rho_0} -l_j \text{ implies } d \models_{\rho_0} -l_i.$$

To show this implication, suppose $d \models_{\rho_0} -l_j$. Since $d \in \mathcal{D}$ is a finite set whereas $\rho_0(l_j)$ contains infinitely many disjoint sets by construction, there must be some (in fact, infinitely many) $d_j \in \rho_0(l_j)$ such that d and d' are disjoint. Thus, using equivalence (25) and Lemma 3.8, we have:

$$\begin{array}{rcl} d \circ d_j \; \in \; \rho_0(b) \\ & = \; \bigcup_{\langle L_i, n_1, n_2 \rangle \Downarrow_M} \llbracket l_i * p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_0} \\ & = \; \bigcup_{\langle L_i, n_1, n_2 \rangle \Downarrow_M} \rho_0(l_i) \cdot \llbracket p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_0}. \end{array}$$

By construction of ρ_0 and using the fact that $d_j \in \rho_0(l_j)$, we must have $d \in \llbracket p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_0}$ for some n_1, n_2 . Moreover, by Lemma 9.2, $d \circ d_j$ uniquely determines $\langle L_j, n_1, n_2 \rangle$, so we must have $\langle L_j, n_1, n_2 \rangle \Downarrow_M$. Since $\langle L_i, n_1, n_2 \rangle \rightsquigarrow_M \langle L_j, n_1, n_2 \rangle$ by applying the goto instruction γ , we then have $\langle L_i, n_1, n_2 \rangle \Downarrow_M$.

Now to see that $d \models_{\rho_0} -l_i$, let $d' \in \mathcal{D}$ be disjoint from d with $d' \in \rho_0(l_i)$. By (25), it suffices to show that $d \circ d' \in \rho_0(b)$. Since $d \in [\![p_1^{n_1} * p_2^{n_2}]\!]_{\rho_0}$, we have $d \circ d' \in [\![l_i * p_1^{n_1} * p_2^{n_2}]\!]_{\rho_0}$ where $\langle L_i, n_1, n_2 \rangle \downarrow_M$, and thus $d \circ d' \in \rho_0(b)$ as required.

Case $\gamma = (L_i: c_1 + +; goto L_j;)$. We have $\kappa(\gamma) = (-(l_j * p_1) - * -l_i)$. As in the previous case, to show $e_0 \models_{\rho_0} \kappa(\gamma)$, we must show that, for any $d \in \mathcal{D}$,

$$d \models_{\rho_0} -(l_j * p_1)$$
 implies $d \models_{\rho_0} -l_i$.

Suppose $d \models_{\rho_0} -(l_j * p_1)$. Since $\rho_0(l_j)$ and $\rho_0(p_1)$ each contain infinitely many disjoint sets, we can find $d_j \in \rho_0(l_j)$ and $d_1 \in \rho_0(p_1)$ such that d, d_j , and d_1 are disjoint. Thus, $d_j \circ d_1 \models_{\rho_0} l_j * p_1$. Using the equivalence (25) and Lemma 3.8, we have:

$$egin{array}{rcl} d\circ d_j\circ d_1 &\in &
ho_0(b) \ &= igcup_{\langle L_i,n_1,n_2
angle \Downarrow_M}
ho_0(l_i)\cdot [\![p_1^{n_1}*p_2^{n_2}]\!]_{
ho_0}. \end{array}$$

By construction of ρ_0 and using the fact that $d_j \in \rho_0(l_j)$, we must have $d \in [\![p_1^{n_1} * p_2^{n_2}]\!]_{\rho_0}$ for some n_1, n_2 . Moreover, by Lemma 9.2, and using the fact that $d_1 \in \rho_0(p_1)$, the set $d \circ d_j \circ d_1$ uniquely determines $\langle L_j, n_1 + 1, n_2 \rangle$, whence $\langle L_j, n_1 + 1, n_2 \rangle \downarrow_M$. Since $\langle L_i, n_1, n_2 \rangle \rightsquigarrow_M \langle L_j, n_1 + 1, n_2 \rangle$ via the increment instruction γ , we have $\langle L_i, n_1, n_2 \rangle \downarrow_M$.

Now, to see that $d \models_{\rho_0} -l_i$, let $d' \in \mathcal{D}$ be disjoint from d with $d' \in \rho_0(l_i)$. By (25), it suffices to show that $d \circ d' \in \rho_0(b)$. Since $d \in [\![p_1^{n_1} * p_2^{n_2}]\!]_{\rho_0}$, we have $d \circ d' \in [\![l_i * p_1^{n_1} * p_2^{n_2}]\!]_{\rho_0}$ where $\langle L_i, n_1, n_2 \rangle \downarrow_M$, and thus $d \circ d' \in \rho_0(b)$ as required.

Case $\gamma = (L_i: c_1 - -; goto L_j;)$. We have $\kappa(\gamma) = (-l_j - -(l_i * p_1))$. To show $e_0 \models_{\rho_0} \kappa(\gamma)$, we must show that, for any $d \in \mathcal{D}$,

$$d \models_{\rho_0} -l_j \text{ implies } d \models_{\rho_0} -(l_i * p_1).$$

Now suppose $d \models_{\rho_0} -l_j$. As in the previous cases, we can find $d_j \in \rho_0(l_j)$ such that d_j and d are disjoint. Thus, using equivalence (25), we have:

$$\begin{aligned} d \circ d_j &\in \rho_0(b) \\ &= \bigcup_{\langle L_i, n_1, n_2 \rangle \Downarrow_M} \rho_0(l_i) \cdot \llbracket p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_0}. \end{aligned}$$

By the same argument as in previous cases, this implies that there exist n_1 and n_2 such that $d \in [\![p_1^{n_1} * p_2^{n_2}]\!]_{\rho_0}$, and $\langle L_j, n_1, n_2 \rangle \Downarrow_M$. Since $\langle L_i, n_1 + 1, n_2 \rangle \rightsquigarrow_M \langle L_j, n_1, n_2 \rangle$ via the decrement instruction γ , we have $\langle L_i, n_1 + 1, n_2 \rangle \Downarrow_M$.

Now let $d' \in \mathcal{D}$ be disjoint from d with $d' \models_{\rho_0} l_i * p_1$. By (25), it suffices to show that $d \circ d' \in \rho_0(b)$. First, we have $d' = d_i \circ d_1$ where $d_i \in \rho_0(l_i)$ and $d_1 \in \rho_0(p_1)$. Since $d \in \llbracket p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_0}$, we have $d \circ d_i \circ d_1 \in \llbracket l_i * p_1^{n_1+1} * p_2^{n_2} \rrbracket_{\rho_0}$ where $\langle L_i, n_1 + 1, n_2 \rangle \Downarrow_M$. Thus, $d \circ d_i \circ d_1 = d \circ d' \in \rho_0(b)$ as required.

Case $\gamma = (L_i: if c_1 = 0 \text{ goto } L_j;)$. In this case, we have $\kappa(\gamma) = (-(l_j \vee l_{-1}) \twoheadrightarrow -l_i)$. To show $e_0 \models_{\rho_0} \kappa(\gamma)$, we must show that, for any $d \in \mathcal{D}$,

$$d \models_{\rho_0} -(l_j \lor l_{-1})$$
 implies $d \models_{\rho_0} -l_i$.

Now suppose that $d \models_{\rho_0} -(l_j \lor l_{-1})$. As in previous cases, we can find $d_j \in \rho_0(l_j)$ and $d_{-1} \in \rho_0(l_{-1})$ such that d, d_j , and d_{-1} are all disjoint. Note that both $d_j \models_{\rho_0} l_j \lor l_{-1}$ and $d_{-1} \models_{\rho_0} l_j \lor l_{-1}$. Thus, using equivalence (25), we have:

$$\begin{aligned} d \circ d_j, d \circ d_{-1} &\in \rho_0(b) \\ &= \bigcup_{\langle L_i, n_1, n_2 \rangle \Downarrow_M} \rho_0(l_i) \cdot \llbracket p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_0}. \end{aligned}$$

By the same argument as in previous cases, there are n_1 and n_2 such that $d \in \llbracket p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_0}$, and we have both $\langle L_j, n_1, n_2 \rangle \Downarrow_M$ and $\langle L_{-1}, n_1, n_2 \rangle \Downarrow_M$. However, by Lemma 7.2, $\langle L_{-1}, n_1, n_2 \rangle \Downarrow_M$ implies $n_1 = 0$. Thus, $\langle L_i, n_1, n_2 \rangle \multimap_M \langle L_j, n_1, n_2 \rangle \Downarrow_M$ by applying the zero-test instruction γ , whence $\langle L_i, n_1, n_2 \rangle \Downarrow_M$. The argument that $d \models_{\rho_0} -l_i$ is then exactly as in the goto and increment instruction cases. This completes the case, and the proof. \Box

LEMMA 9.4. For any machine M we have $e_0 \models_{\rho_0} I \land -l_0$.

PROOF. We trivially have $e_0 \models_{\rho_0} I$. To show $e_0 \models_{\rho_0} -l_0$, taking into account that $e_0 \circ x = x$, we must show that $x \models_{\rho_0} l_0$ implies $x \models_{\rho_0} b$, that is, that $\rho_0(l_0) \subseteq \rho_0(b)$. This is immediate by construction of $\rho_0(b)$, since $\langle L_0, 0, 0 \rangle \Downarrow_M$ by definition and $\rho_0(l_0) = \llbracket l_0 * I * I \rrbracket_{\rho_0} = \llbracket l_0 * p_1^0 * p_2^0 \rrbracket_{\rho_0}$. \Box

THEOREM 9.5. For any machine M, if the sequent

$$(\kappa(M) * l_i * p_1^{n_1} * p_2^{n_2} * (\mathbf{I} \wedge - l_0)) \vdash b$$

is valid in the RAM-domain model $(\mathcal{D}, \circ, \{e_0\})$, then $(L_i, n_1, n_2) \Downarrow_M$.

PROOF. By the definition of validity and using Lemma 3.8, we have:

$$[\![\kappa(M) * l_i * p_1^{n_1} * p_2^{n_2} * (\mathbf{I} \wedge -l_0)]\!]_{\rho_0} \subseteq [\![b]\!]_{\rho_0}$$

i.e., $[\![\kappa(M)]\!]_{\rho_0} \cdot [\![l_i * p_1^{n_1} * p_2^{n_2}]\!]_{\rho_0} \cdot [\![\mathbf{I} \wedge -l_0]\!]_{\rho_0} \subseteq \rho_0(b).$

Since $e_0 \in [\kappa(M)]_{\rho_0}$ by Lemma 9.3 and $e_0 \in [[I \land -l_0]]_{\rho_0}$. by Lemma 9.4 we have in particular:

$$\llbracket l_i * p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_0} \subseteq \rho_0(b).$$

By Lemma 9.2, each of the elements of the set $[[l_i * p_1^{n_1} * p_2^{n_2}]]_{\rho_0}$ uniquely determines the configuration $\langle L_i, n_1, n_2 \rangle$, whence our construction of $\rho_0(b)$ yields $\langle L_i, n_1, n_2 \rangle \downarrow_M$. \Box

9.4. The General Case of Stack-and-Heap-with-Permission Models

Having established as Theorem 9.5 that validity of a sequent of the form $\mathcal{F}_{M,C}$ in the basic RAM-domain model implies termination of machine M from configuration C, we now extend this result to the most sophisticated *stack-and-heap-with-permission* models from Section 2.4. As per Remark 2.1, all the models from Sections 2.1–2.5 can be seen as special instances of such models by taking appropriate locations L, record values RV, stacks S and permission algebra $(P, \bullet, 1)$. Without loss of generality, we consider the infinite set of locations L to be given by \mathbb{N} . We write \circ' for the composition in a stack-and-heap-with-permission model and \cdot' for its extension to sets to disambiguate from the corresponding operations \circ and \cdot of the RAM-domain model.

Definition 9.6. Let $(S \times H, \circ', E)$ be a stack-and-heap model from Section 2.4, where S is a set of stacks and H is a set of heaps-with-permissions from locations $L = \mathbb{N}$ to pairs of record values and permissions in $RV \times P$, where $(P, \bullet, \mathbb{1})$ is a permission algebra. (Recall that $\mathbb{1} \bullet \pi$ is undefined for all $\pi \in P$.) We abuse notation slightly by writing the unit e_0 of the RAM-domain model for the heap with empty domain. Thus, $E = \{\langle s, e_0 \rangle \mid s \in S\}$.

Based on our valuation ρ_0 for the RAM-domain model and a given machine M in Definition 9.1, we introduce a valuation ρ_1 for $(S \times H, \circ', E)$ as follows. First, we fix an arbitrary stack $s_0 \in S$, and for each finite set $d \subseteq \mathbb{N}$ we define the set $[d] \subseteq S \times H$ by:

$$[d] = \{ \langle s_0, h \rangle \mid \texttt{domain}(h) = d \text{ and } \forall \ell \in d. \ h(\ell) = \langle -, \mathbb{1} \rangle \}.$$

where $h(\ell) = \langle ., 1 \rangle$ means that $h(\ell) = \langle s, 1 \rangle$ for some $s \in S$. Then, for any atomic proposition p, we define its valuation by:

$$\rho_1(p) = \bigcup_{d \in \rho_0(p)} [d].$$

LEMMA 9.7. For any stack-and-heap model $(S \times H, \circ', E)$ and any atomic propositions p and q, we have the following identity:

$$\llbracket p * q
rbracket_{
ho_1} = igcup_{d \in \llbracket p * q
rbracket_{
ho_0}} [d].$$

J. Brotherston and M. Kanovich

PROOF. First, we show that for any $d_1 \in \rho_0(p), d_2 \in \rho_0(q)$,

$$[d_1 \circ d_2] = [d_1] \cdot [d_2]. \tag{26}$$

For disjoint d_1 and d_2 , this is given by construction, since

$$\begin{split} [d_1] \cdot' [d_2] &= \{ \langle s_0, h_1 \rangle \circ' \langle s_0, h_2 \rangle \mid \langle s_0, h_1 \rangle \in [d_1], \langle s_0, h_2 \rangle \in [d_2] \} \\ &= \{ \langle s_0, h_1 \rangle \circ' \langle s_0, h_2 \rangle \mid \text{domain}(h_1) = [d_1], \text{domain}(h_2) = [d_2], \\ &\quad \forall \ell \in d_1. \ h_1(\ell) = \langle_{-}, \mathbb{1} \rangle, \forall \ell \in d_2. \ h_2(\ell) = \langle_{-}, \mathbb{1} \rangle \} \\ &= \{ \langle s_0, h \rangle \mid \text{domain}(h) = d_1 \circ d_2, \forall \ell \in d_1 \circ d_2. \ h(\ell) = \langle_{-}, \mathbb{1} \rangle \} \\ &= [d_1 \circ d_2]. \end{split}$$

For overlapping d_1 and d_2 , we have $d_1 \circ d_2$ undefined and thus $[d_1 \circ d_2] = \emptyset$. We show that $[d_1]$ $(d_2) = \emptyset$. Assume for contradiction that $\langle s_0, h_1 \rangle \circ \langle s_0, h_2 \rangle$ is defined for some $\langle s_0, h_1 \rangle \in [d_1]$ and $\langle s_0, h_2 \rangle \in [d_2]$. By construction of $[d_1]$ and $[d_2]$, and since d_1 , d_2 are overlapping, this implies $h_1(\ell) = h_2(\ell) = \langle ., 1 \rangle$ for some $\ell \in d_1 \cap d_2$. But then since $\langle s_0, h_1 \rangle$ or $\langle s_0, h_2 \rangle$ is defined, we must have $\mathbb{1} \bullet \mathbb{1}$ defined (because in heap-withpermissions models (cf. Section 2.3) we add the permissions when composing compatible heaps), which is a contradiction. Thus, $[d_1] \cdot [d_2]$ is empty when $d_1 \circ d_2$ is undefined.

Now, using Lemma 3.8, we have as required:

$$\begin{split} \llbracket p * q \rrbracket_{\rho_1} &= \llbracket p \rrbracket_{\rho_1} \cdot' \llbracket q \rrbracket_{\rho_1} \\ &= \{ \langle s_0, h_1 \rangle \circ' \langle s_0, h_2 \rangle \mid \langle s_0, h_1 \rangle \in \rho_1(p), \langle s_0, h_2 \rangle \in \rho_1(q) \} \\ &= \{ \langle s_0, h_1 \rangle \circ' \langle s_0, h_2 \rangle \mid \langle s_0, h_1 \rangle \in \bigcup_{d \in \rho_0(p)} [d], \langle s_0, h_2 \rangle \in \bigcup_{d \in \rho_0(q)} [d] \} \\ &= \bigcup_{d_1 \in \rho_0(p), \ d_2 \in \rho_0(q)} \{ \langle s_0, h_1 \rangle \circ' \langle s_0, h_2 \rangle \mid \langle s_0, h_1 \rangle \in [d_1], \langle s_0, h_2 \rangle \in [d_2] \} \\ &= \bigcup_{d_1 \in \rho_0(p), \ d_2 \in \rho_0(q)} [d_1] \cdot' [d_2] \\ &= \bigcup_{d_1 \in \rho_0(p), \ d_2 \in \rho_0(q)} [d_1 \circ d_2] \qquad (by (26)) \\ &= \bigcup_{d \in [n]_{\rho_0} \cdot \llbracket q \rrbracket_{\rho_0}} [d] \\ &= \bigcup_{d \in \llbracket p * q \rrbracket_{\rho_0}} [d]. \quad \Box \end{split}$$

LEMMA 9.8. For any stack-and-heap model $(S \times H, \circ', E)$ and any formula A of the form l_i , $l_i * p_k$, or $l_i \lor l_j$, we have the equivalence

$$\llbracket A
rbracket_{
ho_1} \cdot' \left\{ \langle s_0, h
angle
ight\} \subseteq \llbracket b
rbracket_{
ho_1} \, \Leftrightarrow \, \langle s_0, h
angle \in \llbracket d
rbracket \, and \, \llbracket A
rbracket_{
ho_0} \cdot \{d\} \subseteq \llbracket b
rbracket_{
ho_0}.$$

where d = domain(h).

-

т

PROOF. First, note that by distinguishing cases on A, and using Lemma 9.7 in the case $A = l_i * p_k$, we easily have that

$$\llbracket A \rrbracket_{\rho_1} = \bigcup_{d \in \llbracket A \rrbracket_{\rho_0}} [d].$$
⁽²⁷⁾

We show each of the required implications separately.

$$(\Rightarrow) \text{ Suppose that } \llbracket A \rrbracket_{\rho_1} \cdot' \{ \langle s_0, h \rangle \} \subseteq \llbracket b \rrbracket_{\rho_1}. \text{ That is, we have:} \\ \{ \langle s', h' \rangle \circ' \langle s_0, h \rangle \mid \langle s', h' \rangle \models_{\rho_1} A \} \subseteq \bigcup_{d \in \rho_0(b)} [d].$$
(28)

Now let d = domain(h), and let $x \in \llbracket A \rrbracket_{\rho_0} \cdot \{d\}$. Thus, $x = d \circ d'$, where d and d' are disjoint and $d' \models_{\rho_0} A$. We require to show that $d \circ d' \in \llbracket b \rrbracket_{\rho_0}$ and $\langle s_0, h \rangle \in [d]$.

Let $\langle s_0, h' \rangle \in [d']$. Since $d' \in [\![A]\!]_{\rho_0}$, we have by (27) $\langle s_0, h' \rangle \in [\![A]\!]_{\rho_1}$, that is, $\langle s_0, h' \rangle \models_{\rho_1} A$. Since d and d' are disjoint, $\langle s_0, h \rangle \circ' \langle s_0, h' \rangle$ is defined and, by (28),

$$\langle s_0, h \rangle \circ' \langle s_0, h' \rangle \in \bigcup_{d \in \rho_0(b)} [d].$$

That is, $\langle s_0, h \rangle \circ' \langle s_0, h' \rangle \in [d'']$ for some $d'' \in \rho_0(b)$. Since the domain of $\langle s_0, h \rangle \circ' \langle s_0, h' \rangle$ is $d \circ d'$ by construction, we must have $d'' = d \circ d'$. Thus, $d \circ d' \in \rho_0(b) = [\![b]\!]_{\rho_0}$ as required. Furthermore, $\langle s_0, h \rangle \in [d]$ because d and d' are disjoint, and thus h and h' do not overlap, but $\langle s_0, h \rangle \circ' \langle s_0, h' \rangle \in [d \circ d']$, which means that $h(\ell) = \langle ., 1 \rangle$ for all $\ell \in d$. This completes the "only if" direction.

 (\Leftarrow) Let d = domain(h), let $\langle s_0, h \rangle \in [d]$ and suppose $[\![A]\!]_{\rho_0} \cdot \{d\} \subseteq [\![b]\!]_{\rho_0}$. The latter inclusion means that:

$$\{d' \circ d \mid d' \models_{\rho_0} A\} \subseteq \rho_0(b). \tag{29}$$

Now suppose that $x \in \llbracket A \rrbracket_{\rho_1} \cdot \{ \langle s_0, h \rangle \}$. Thus, $x = \langle s', h' \rangle \circ' \langle s_0, h \rangle$ (which implies $s' = s_0$), where $\langle s', h' \rangle \models_{\rho_1} A$. We require to show that $\langle s_0, h' \rangle \circ' \langle s_0, h \rangle \in \llbracket b \rrbracket_{\rho_1}$.

Since $\langle s_0, h' \rangle \in [\![A]\!]_{\rho_1}$, we have by (27) some d' such that $d' \in [\![A]\!]_{\rho_0}$, that is, $d' \models_{\rho_0} A$, and $\langle s_0, h' \rangle \in [d']$ (which implies domain(h') = d'). Because $\langle s_0, h \rangle \in [d]$ and $\langle s', h' \rangle \in [d']$, we have $h(\ell) = \langle _, 1 \rangle$ for all $\ell \in d$ and $h'(\ell') = \langle _, 1 \rangle$ for all $\ell' \in d'$. As $\langle s_0, h' \rangle \circ' \langle s_0, h \rangle$ is defined by assumption, it follows that h and h' cannot overlap, and so d and d' are disjoint. Thus, by (29), $d' \circ d \in \rho_0(b)$. We easily have $\langle s_0, h' \rangle \circ' \langle s_0, h \rangle \in [d' \circ d]$, and so

$$\langle s_0, h' \rangle \circ' \langle s_0, h \rangle \in \bigcup_{d \in \rho_0(b)} [d] = \rho_1(b) = \llbracket b \rrbracket_{\rho_1}$$

as required. This completes the "if" direction, and the proof. \Box

LEMMA 9.9. $\langle s_0, e_0 \rangle \models_{\rho_1} \kappa(M)$ for any machine M and any stack-and-heap model $(S \times H, \circ', E)$.

PROOF. As in Lemma 9.3, we show that $\langle s_0, e_0 \rangle \models_{\rho_1} \kappa(\gamma)$ for any instruction γ in Definition 7.1. For any such γ , the formula $\kappa(\gamma)$ is of the form $(-A \twoheadrightarrow -B)$ where A and B are of the form $l_i, l_i \lor l_j$ or $l_i * p_k$. Since $\langle s_0, e_0 \rangle$ is a unit of the model and $\langle s_0, e_0 \rangle \circ' \langle s, h \rangle$ is undefined for $s \neq s_0$, we have

$$\langle s_0, e_0 \rangle \models_{\rho_1} \neg A \twoheadrightarrow \neg B$$

 $\Leftrightarrow \forall \langle s,h \rangle. \langle s_0,e_0 \rangle \circ' \langle s,h \rangle \text{ defined and } \langle s,h \rangle \models_{\rho_1} \neg A \text{ implies } \langle s_0,e_0 \rangle \circ' \langle s,h \rangle \models_{\rho_1} \neg B$

- $\Leftrightarrow \ \forall \langle s', h' \rangle. \ s = s_0 \ \text{and} \ \langle s, h \rangle \models_{\rho_1} \neg A \ \text{implies} \ \langle s, h \rangle \models \neg B$
- $\Leftrightarrow \forall h. \langle s_0, h \rangle \models_{\rho_1} \neg A \text{ implies } \langle s_0, h \rangle \models_{\rho_1} \neg B.$

Recalling that $\neg A = A \twoheadrightarrow b$, and using Lemma 3.8, this amounts to showing, for any $h \in H$:

$$\llbracket A \rrbracket_{\rho_1} \cdot \{ \langle s_0, h \rangle \} \subseteq \llbracket b \rrbracket_{\rho_1} \Rightarrow \llbracket B \rrbracket_{\rho_1} \cdot \{ \langle s_0, h \rangle \} \subseteq \llbracket b \rrbracket_{\rho_1}.$$
(30)

Assume $\llbracket A \rrbracket_{\rho_1} \cdot' \{\langle s_0, h \rangle\} \subseteq \llbracket b \rrbracket_{\rho_1}$, and let d = domain(h). By Lemma 9.8, we have $\langle s_0, h \rangle \in \llbracket d \rrbracket$, and $\llbracket A \rrbracket_{\rho_0} \cdot \{d\} \subseteq \llbracket b \rrbracket_{\rho_0}$. By Lemma 9.3, we have $e_0 \models_{\rho_0} \kappa(\gamma)$ and thus (by the same reasoning as above) $\llbracket -A \rrbracket_{\rho_0} \subseteq \llbracket -B \rrbracket_{\rho_0}$, which means that $\llbracket A \rrbracket_{\rho_0} \cdot \{d\} \subseteq \llbracket b \rrbracket_{\rho_0}$ implies $\llbracket B \rrbracket_{\rho_0} \cdot \{d\} \subseteq \llbracket b \rrbracket_{\rho_0}$. Thus, we have $\llbracket B \rrbracket_{\rho_0} \cdot \{d\} \subseteq \llbracket b \rrbracket_{\rho_0}$, whence Lemma 9.8 yields $\llbracket B \rrbracket_{\rho_1} \cdot' \{\langle s_0, h \rangle\} \subseteq \llbracket b \rrbracket_{\rho_1}$, as required. \Box

LEMMA 9.10. $\langle s_0, e_0 \rangle \models_{\rho_1} I \land \neg l_0$ for any machine M and any stack-and-heap model $(S \times H, \circ', E)$.

PROOF. We have $\langle s_0, e_0 \rangle \models_{\rho_1} I$ because $\langle s_0, e_0 \rangle \in E$. By Lemma 9.4, we have $e_0 \models_{\rho_0} -l_0$ and thus $\rho_0(l_0) \subseteq \rho_0(b)$. Thus, we have

$$\rho_1(l_0) = \bigcup_{d \in \rho_0(l_0)} [d] \subseteq \bigcup_{d \in \rho_0(b)} [d] = \rho_1(b),$$

which implies that $\langle s_0, e_0 \rangle \models_{\rho_1} - l_0$, as required. \Box

Journal of the ACM, Vol. 61, No. 2, Article 14, Publication date: April 2014.

THEOREM 9.11. For any machine M and configuration (L_i, n_1, n_2) , if a sequent $\mathcal{F}_{M, (L_i, n_1, n_2)}$ of the form

$$\kappa(M) * l_i * p_1^{n_1} * p_2^{n_2} * (\mathbf{I} \wedge -l_0) \vdash b$$

is valid in some concrete model listed in Section 2 then $(L_i, n_1, n_2) \Downarrow_M$.

PROOF. The case of Petri net marking models (Section 2.7) and integer partition models (Section 2.6) with their *total* \circ can be covered by the original valuation ρ_0 from Definition 9.1. See also Section 9.5.

For other models, by taking appropriate locations L, record values RV, set of stacks S and permission algebra P (where L is infinite), we may assume that $\mathcal{F}_{M, \langle L_i, n_1, n_2 \rangle}$ is valid in a stack-and-heap model ($S \times H, \circ', E$) as given in Definition 9.6. Thus, we have by definition of validity, and using Lemma 3.8:

$$\llbracket \kappa(M) * l_i * p_1^{n_1} * p_2^{n_2} * (I \wedge -l_0) \rrbracket_{
ho_1} \subseteq \llbracket b \rrbracket_{
ho_1}$$

that is, $\llbracket \kappa(M) \rrbracket_{
ho_1} \cdot ' \llbracket l_i * p_1^{n_1} * p_2^{n_2} \rrbracket_{
ho_1} \cdot ' \llbracket I \wedge -l_0 \rrbracket_{
ho_1} \subseteq
ho_1(b).$

Taking into account that $\langle s_0, e_0 \rangle \in [[\kappa(M)]]_{\rho_1}$ and $\langle s_0, e_0 \rangle \in [[I \land -l_0]]_{\rho_1}$ according to Lemmas 9.9 and 9.10, respectively, we get:

$$\llbracket l_i * p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_1} \subseteq \rho_1(b).$$

Using Lemma 9.7 and our definition of $\rho_1(b)$, we obtain:

$$\bigcup_{d \in \llbracket l_i * p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_0}} [d] \subseteq \bigcup_{d \in \rho_0(b)} [d].$$

According to Lemma 9.2, each element from the set $[l_i * p_1^{n_1} * p_2^{n_2}]_{\rho_0}$ uniquely determines the configuration $\langle L_i, n_1, n_2 \rangle$, so that our construction of $\rho_0(b)$ yields $\langle L_i, n_1, n_2 \rangle \Downarrow_M$. \Box

9.5. Valuation for the Total Multiset Model over a Fixed Finite Set L

By the same token, we can prove that the following simplified valuation ρ_{mult} provides the desired undecidability results for the total multiset model of Section 2.6 even for the finite multisets over a fixed finite set L. That is, we have $\langle L_i, n_1, n_2 \rangle \downarrow_M$ whenever the following sequent $\mathcal{F}_{M, \langle L_i, n_1, n_2 \rangle}$ is valid in this particular total model:

$$\kappa(M)*l_i*p_1^{n_1}*p_2^{n_2}*(\mathbf{I}\wedge -l_0)\vdash b.$$

Definition 9.12. Given a machine M, we introduce the following valuation ρ_{mult} for the finite multisets over a fixed finite set L of Section 2.6:

$$\rho_{mult}(p_1) = \{ \{2\} \}$$

$$\rho_{mult}(p_2) = \{ \{3\} \}$$

$$\rho_{mult}(l_i) = \{ \{2i+9\} \},$$

where $i \geq -2$, and

$$\rho_{mult}(b) = \bigcup_{\langle L_i, n_1, n_2 \rangle \downarrow_M} \llbracket l_i * p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_{mult}},$$

where *b* is the distinguished propositional variable introduced in Definition 7.3. (The reason behind our choice for $\rho_{mult}(b)$ is given in Section 7.1.)

In fact, the cardinality of the *finite* L is proportional to the number of states of a universal Minsky machine.

According to Section 9.2, for our practical heap-like models with their peculiar "disjoint heap composition", the corresponding L is necessarily *infinite*, in order to guarantee that the valuations of the "counter propositions" p_1 and p_2 have infinitely many disjoint elements.

10. FINITE APPROXIMATIONS IN INFINITE MODELS

At first sight, our undecidability results for propositional separation logic seem to be at odds with the decidability of the quantifier-free fragment of a certain separation theory over an infinite heap model, due to Calcagno et al. [2001].

However, the crucial difference between our setting and theirs is that their decidability result is restricted to specific *finite* valuations ρ such that $\rho(p)$ is finite for every atomic proposition p. More precisely, in Calcagno et al. [2001] each p represents one *cell*, that is, a heap whose domain is a singleton. Their decidability result is nevertheless highly non-trivial because their language contains -* and the underlying separation model employs a nontotal \circ , so that, for example, whenever $[\![A]\!]_{\rho}$ is *finite*, $[\![A -* B]\!]_{\rho}$ becomes *infinite*. Here, we investigate this phenomenon.

LEMMA 10.1. Let $(H, \circ, \{e_0\})$ be a heap model from Section 2.1. There is an algorithm that, for any finite valuation ρ , decides whether $e_0 \models_{\rho} \kappa(M)$ holds or not.

Proof. In principle, this result can be deduced from Calcagno et al. [2001]. The following direct construction illustrates subtleties of the problem, caused by non-totality of the composition \circ .

As in Lemmas 9.3 and 9.9, we have to check whether

$$e_0 \models_{\rho} \kappa(\gamma)$$

for any machine instruction γ taken from Definition 7.1. For any such γ , the formula $\kappa(\gamma)$ is of the form $(-A \twoheadrightarrow -B)$ where *A* and *B* are each of the form l_i , $(l_i \lor l_j)$ or $(l_i * p_k)$. Note that, as ρ is a finite valuation, $[A]_{\rho}$ and $[B]_{\rho}$ are also finite.

Checking whether $e_0 \models_{\rho} \kappa(\gamma)$ thus means checking whether the following sentence is true or not (cf. (19)):

for all
$$h \in H$$
, $\llbracket A \rrbracket_{\rho} \cdot \{h\} \subseteq \rho(b)$ implies $\llbracket B \rrbracket_{\rho} \cdot \{h\} \subseteq \rho(b)$. (31)

By negating this statement, it suffices to check whether or not there is an $h \in H$ satisfying the following sentence:

$$\llbracket A \rrbracket_{\rho} \cdot \{h\} \subseteq \rho(b) \text{ and } \llbracket B \rrbracket_{\rho} \cdot \{h\} \not\subseteq \rho(b).$$
(32)

The tricky point, caused by the fact that \circ is not total, is that the Eq. (32) may have an infinite number of solutions *h*. Nevertheless, we can construct, in advance, two finite sets $\mathcal{H}_1, \mathcal{H}_2 \subseteq H$ such that, if Eq. (32) has a solution, then it has a solution \tilde{h} belonging to the finite set $\mathcal{H}_1 \cup \mathcal{H}_2$.

In other words, statement (31), in which the range of the quantified h is infinite, is equivalent to the following decidable statement, in which the finite range $\mathcal{H}_1 \cup \mathcal{H}_2$ of the quantified h can be computed in advance:

for all
$$h \in \mathcal{H}_1 \cup \mathcal{H}_2$$
, $\llbracket A \rrbracket_{\rho} \cdot \{h\} \subseteq \rho(b)$ implies $\llbracket B \rrbracket_{\rho} \cdot \{h\} \subseteq \rho(b)$. (33)

The practical upshot of this transformation is that checking whether $e_0 \models_{\rho} \kappa(\gamma)$ can be done in a finite number of steps. It just remains to show how to construct the finite sets \mathcal{H}_1 and \mathcal{H}_2 .

Let $\llbracket A \rrbracket_{\rho} = \{f_1, f_2, \dots, f_m\}$ and $\llbracket B \rrbracket_{\rho} = \{g_1, \dots, g_t\}$. Given a solution *h* to (32), we consider two cases depending on whether or not $\llbracket A \rrbracket_{\rho} \cdot \{h\} = \emptyset$.

—Case $[\![A]\!]_{\rho} \cdot \{h\} \neq \emptyset$. In this case, the product $f_i \circ h$ must be defined for some *i*, and, by (32), we have $f_i \circ h \in \rho(b)$. Thus, *h* is guaranteed to belong to the *finite* set \mathcal{H}_1 of all "sub-heaps" of $\rho(b)$, defined as follows:

$$\mathcal{H}_1 = \{h \in H \mid \exists h' \in H. \ h' \circ h \in \rho(b)\}.$$

-*Case* $[\![A]\!]_{\rho} \cdot \{h\} = \emptyset$. In this case, for each *i* such that $1 \le i \le m$, the product $f_i \circ h$ is undefined and hence there is an ℓ_i such that $\ell_i \in \text{domain}(f_i) \cap \text{domain}(h)$. Notice that, by (32), we have $[\![B]\!]_{\rho} \cdot \{h\} \not\subseteq \rho(b)$. Consequently, for some $1 \le j \le t$, we have

$$\operatorname{domain}(g_i) \cap \{\ell_1, \ell_2, \dots, \ell_m\} = \emptyset.$$
(34)

(Otherwise, for all j we have that domain $(g_j) \cap \{\ell_1, \ell_2, \dots, \ell_m\} \neq \emptyset$, and thereby domain $(g_j) \cap$ domain $(h) \neq \emptyset$, resulting in $[\![B]\!]_{\rho} \cdot \{h\} = \emptyset$, which contradicts (32).)

Now we construct a new solution \tilde{h} in the following way. Let \tilde{a} be a fresh element of L such that \tilde{a} does not occur in $[\![A]\!]_{\rho}$, $[\![B]\!]_{\rho}$ or $\rho(b)$, and let \tilde{b} be a fixed element of RV. Then, the domain of \tilde{h} is defined as the extended set $\{\ell_1, \ell_2, \ldots, \ell_m, \tilde{a}\}$, and for each x from domain (\tilde{h}) we set:

$$\widetilde{h}(x) = \widetilde{b}.$$

It remains to show that \tilde{h} indeed satisfies the sentence (32).

First, for all $1 \le i \le m$, we have domain $(f_i) \cap \text{domain}(\tilde{h}) \ne \emptyset$ because $\ell_i \in \text{domain}(\tilde{h})$ by construction. This implies that $[\![A]\!]_{\rho} \cdot \{\tilde{h}\} = \emptyset$.

Second, by (34), domain(g_j) and domain(\tilde{h}) are disjoint for some $1 \leq j \leq t$, so that $g_j \circ \tilde{h}$ is defined and, because of the choice of \tilde{a} , we have $g_j \circ \tilde{h} \notin \rho(b)$, so $[\![B]\!]_{\rho} \cdot \{\tilde{h}\} \not\subseteq \rho(b)$. Therefore, we can conclude that \tilde{h} is still a solution to (32).

Therefore, we can conclude that \tilde{h} is still a solution to (32). Now we define a set \mathcal{H}_2 of "solution candidates" as follows. For each choice of ℓ_1 , ℓ_2, \ldots, ℓ_m from domain (f_1) , domain $(f_2), \ldots$, domain (f_m) , respectively, \mathcal{H}_2 contains the heap h' defined as follows:

domain
$$(h') = \{\ell_1, \ell_2, \dots, \ell_m, \widetilde{a}\}$$
 and $\forall x \in \text{domain}(h')$. $h'(x) = b$.

It is clear that \mathcal{H}_2 is finite and contains every solution of the form \tilde{h} , as required. This completes the proof. \Box

THEOREM 10.2. Let $(H, \circ, \{e_0\})$ be a heap model from Section 2.1. Then, there is an algorithm that, for any finite valuation ρ , and any sequent $\mathcal{F}_{M,(L_i,n_1,n_2)}$ of the form:

$$\kappa(M) * l_i * p_1^{n_1} * p_2^{n_2} * (\mathbf{I} \wedge -l_0) \vdash b.$$

decides whether this sequent is valid under the valuation ρ .

PROOF. Given an $\mathcal{F}_{M,\langle L_i,n_1,n_2\rangle}$, we first use Lemma 10.1 to compute $[\![\kappa(M)]\!]_{\rho}$ and $[\![I \wedge -l_0]\!]_{\rho}$ (note that each of these is either empty, or the singleton set $\{e_0\}$). If either of these sets is empty, then trivially $\mathcal{F}_{M,\langle L_i,n_1,n_2\rangle}$ is valid under the valuation ρ . Otherwise, $[\![\kappa(M)]\!]_{\rho} = [\![I \wedge -l_0]\!]_{\rho} = \{e_0\}$, so deciding the validity of $\mathcal{F}_{M,\langle L_i,n_1,n_2\rangle}$ under

Otherwise, $[\kappa(M)]_{\rho} = [1 \land -l_0]_{\rho} = \{e_0\}$, so deciding the validity of $\mathcal{F}_{M, \langle L_i, n_1, n_2 \rangle}$ under ρ means deciding the inclusion

$$\begin{split} & [\![\kappa(M)*l_i*p_1^{n_1}*p_2^{n_2}*(\mathrm{I}\wedge -l_0)]\!]_\rho \subseteq \rho(b) \\ & \text{that is,} \ [\![\kappa(M)]\!]_\rho \cdot [\![l_i*p_1^{n_1}*p_2^{n_2}]\!]_\rho \cdot [\![(\mathrm{I}\wedge -l_0)]\!]_\rho \subseteq \rho(b) \\ & \text{that is,} \qquad \{e_0\} \cdot [\![l_i*p_1^{n_1}*p_2^{n_2}]\!]_\rho \cdot \{e_0\} \subseteq \rho(b) \\ & \text{that is,} \qquad [\![l_i*p_1^{n_1}*p_2^{n_2}]\!]_\rho \subseteq \rho(b) \end{split}$$

which is straightforward since both $[[l_i * p_1^{n_1} * p_2^{n_2}]]_{\rho}$ and $\rho(b)$ are finite. \Box

10.1. Noncompactness

COROLLARY 10.3. We can construct a sequent $\mathcal{F}_{M,(L_1,n_0,0)}$ of the form

$$\kappa(M) * l_1 * p_1^{n_0} * (\mathbf{I} \wedge -l_0) \vdash b$$

so that, for each heap model $(H, \circ, \{e_0\})$ from Section 2.1,

- (a) $\mathcal{F}_{M,(L_1,n_0,0)}$ is not valid in this model (and hence the corresponding computation of M from $\langle L_1, n_0, 0 \rangle$ does not terminate),
- (b) but $\mathcal{F}_{M,(L_1,n_0,0)}$ is valid in this model under all finite valuations ρ .

PROOF. Take M such that $K_M =_{def} \{n \mid (L_1, n, 0) \downarrow M\}$ is undecidable (the existence of such machines is guaranteed by Minsky [1967]). K_M is recursively enumerable.

Now let $(H, \circ, \{e_0\})$ be a heap model from Section 2.1. According to Figure 1 in Section 5, we have

$$\begin{array}{l} K_M \ = \ \{n \mid \mathcal{F}_{M, \langle L_1, n, 0 \rangle} \text{ provable in Minimal BBI} \} \\ = \ \{n \mid \mathcal{F}_{M, \langle L_1, n, 0 \rangle} \text{ valid in all separation models} \} \\ = \ \{n \mid \mathcal{F}_{M, \langle L_1, n, 0 \rangle} \text{ valid in } (H, \circ, \{e_0\}) \}. \end{array}$$

Next, we define

 $W_M =_{\text{def}} \{n \mid \mathcal{F}_{M, (L_1, n, 0)} \text{ is not valid in } (H, \circ, \{e_0\}) \text{ under some finite valuation } \rho\}.$

By Theorem 10.2, W_M is also recursively enumerable.

However, by construction, K_M and W_M are disjoint. Moreover, since K_M is recursively enumerable but undecidable, W_M is not the whole complement of K_M . Therefore, we can find a number n_0 such that $n_0 \notin K_M \cup W_M$. We can now complete the two parts of the corollary as follows:

- (a) Since $n_0 \notin K_M$, Theorem 9.11 implies that $\mathcal{F}_{M,(L_1,n_0,0)}$ is not valid in $(H, \circ, \{e_0\})$.
- (b) However, $n_0 \notin W_M$ implies that $\mathcal{F}_{M, \langle L_1, n_0, 0 \rangle}$ is valid in $(H, \circ, \{e_0\})$ under all finite valuations ρ . \Box

11. EXTENSION TO CLASSICAL BI

In this section, we extend our undecidability results to the class of "dualising separation models", whose proof-theoretical basis is given by the bunched logic Classical BI.

Definition 11.1. A CBI-*model* is given by $(H, \circ, e, \cdot^{-1})$, where $(H, \circ, \{e\})$ is a separation model (with a single unit *e*) and $\cdot^{-1} : H \to H$ satisfies $h \circ h^{-1} = e^{-1}$ for all $h \in H$.

The CBI-models we consider here form a subclass of the more general *relational* CBI-models given in Brotherston and Calcagno [2010].

Example 11.2. Examples of CBI-Models (cf. Brotherston and Calcagno [2010]).

- (a) ([0, 1], \circ , 0, \cdot^{-1}), where $x_1 \circ x_2$ is $x_1 + x_2$ but undefined when $x_1 + x_2 > 1$. The inverse x^{-1} is 1 x.
- (b) $(\Sigma, \circ, \varepsilon, \overline{\cdot})$ where Σ is any class of languages containing the empty language ε and closed under union \cup and complement $\overline{\cdot}$. Here $d_1 \circ d_2$ is the union of disjoint languages d_1 and d_2 (in the overlapping case, $d_1 \circ d_2$ is undefined). For example, Σ may be the class of regular languages, or the class of finite and co-finite sets.
- (c) *Effect algebras* [Foulis and Bennett 1994], which arise in the foundations of quantum mechanics, are exactly CBI-models with indivisible units.
- (d) *Permission algebras* $(P, \bullet, 1)$ [Bornat et al. 2005] enriched with a "formal unit" e and "formal equalities" $e \bullet h = h \bullet e = e$ can be shown to be exactly nondegenerate (i.e., having more than one element) CBI-models with indivisible units.

Definition 11.3. Following Definition 4.1, we introduce a second chain of logics as follows:

$$BBI \subseteq CBI \subseteq CBI + eW \subseteq CBI + W.$$

- --*Classical* BI, a.k.a. CBI Brotherston and Calcagno [2010] is obtained from BBI by extending its language with a constant \widetilde{I} , and adding the axiom $\sim A \vdash A$, where $\sim A$ is an abbreviation for $(A \twoheadrightarrow \widetilde{I})$.
- --CBI+eW is obtained by extending CBI with the restricted *-weakening $I \land (A * B) \vdash A$.

—CBI+W is obtained by extending CBI with the unrestricted *-weakening $A * B \vdash A$.

Validity of CBI-formulas with respect to CBI-models $(H, \circ, e, \cdot^{-1})$ is given by extending the satisfaction relation in Definition 3.9 with the clause:

$$h \models_{\rho} \widetilde{\mathbf{I}} \Leftrightarrow h \neq e^{-1}.$$

PROPOSITION 11.4. If A is provable in CBI, then A is valid in all CBI-models, and if A is provable in CBI+eW, then A is valid in all CBI-models with indivisible units.

PROOF. Since CBI-models are special cases of separation models, and BBI is sound wrt. separation models (Proposition 4.2), it suffices to show for the first part that the CBI axiom $\sim A \vdash A$ is valid in an arbitrary CBI-model $(H, \circ, e, \cdot^{-1})$.

First, we observe that for any $h \in H$, the element h^{-1} is the *unique* element such that $h \circ h^{-1} = e^{-1}$. For suppose that $h \circ x = e^{-1}$, then we have by associativity and commutativity of \circ :

$$e^{-1} \circ x = (h \circ h^{-1}) \circ x = (h \circ x) \circ h^{-1} = e^{-1} \circ h^{-1},$$

whence we obtain $x = h^{-1}$ by cancellativity³ of \circ . As an immediate corollary, we also have $(h^{-1})^{-1} = h$.

Now by the definition of validity and recalling that $\sim A =_{def} (A \twoheadrightarrow \widetilde{I})$, we have:

 $h \models_{\rho} \sim A \Leftrightarrow \forall h'. h \circ h' \text{ defined and } h' \models_{\rho} A \text{ implies } h \circ h' \neq e^{-1}.$

Since h^{-1} is the unique element of *H* such that $h \circ h^{-1} = e^{-1}$, we obtain:

$$h\models_{
ho}\sim A \Leftrightarrow h^{-1}
ot\models_{
ho} A.$$

Thus, using the fact that $(h^{-1})^{-1} = h$, we have:

$$h \models_{\rho} \sim \sim A \ \Leftrightarrow \ h^{-1} \not\models_{\rho} \sim A \ \Leftrightarrow \ (h^{-1})^{-1} \models_{\rho} A \ \Leftrightarrow \ h \models_{\rho} A$$

and so $\sim \sim A \vdash A$ (as well as its converse) is valid as required.

For soundness of CBI+eW, the fact that restricted *-weakening holds in all CBImodels with indivisible units follows from the fact that it holds in all separation models with indivisible units, as established in Proposition 4.2. \Box

COROLLARY 11.5. Interpreting \subset as strict inclusion between the set of sequents provable in each system using only the language of BBI, we have:

$$BBI \subset CBI \subset CBI + eW \subset CBI + W.$$

PROOF. The nonstrict versions of the inclusions hold easily by construction. The noninclusion CBI $\not\subseteq$ BBI was established in Brotherston and Calcagno [2010]. By the

³The original definition of a CBI-model in Brotherston and Calcagno [2010] requires as an axiom that the dual h^{-1} be unique for each h, whereas here we drop this requirement in favour of cancellativity of \circ , which is arguably more natural.

same arguments as in Theorem 3.10 and Corollary 4.4, restricted *-weakening is not valid in all CBI-models, and unrestricted *-weakening is not valid in all CBI-models with indivisible units. Thus, the noninclusions $CBI+W \not\subseteq CBI+eW \not\subseteq CBI$ hold by Proposition 11.4. \Box

PROPOSITION 11.6. CBI+W is ordinary classical logic.

PROOF. By the same argument as in Proposition 4.7, the presence of unrestricted *-weakening forces the equivalences $A * B \equiv A \land B$, $A \twoheadrightarrow B \equiv A \rightarrow B$ and $I \equiv \top$.

It just remains to show that $I \equiv \bot$. To see this, first note that $\bot \vdash I$ is trivially provable by the usual *ex falso quodlibet* of classical logic. For the reverse direction, first note that $(\bot \twoheadrightarrow \widetilde{I}) \vdash \top$ is trivially provable. As a consequence, $(\top \twoheadrightarrow \widetilde{I}) \vdash ((\bot \twoheadrightarrow \widetilde{I}) \twoheadrightarrow \widetilde{I})$ is also provable. By the CBI axiom, we have $((\bot \twoheadrightarrow \widetilde{I}) \twoheadrightarrow \widetilde{I}) \vdash \bot$, whence by transitivity of \vdash we obtain $(\top \twoheadrightarrow \widetilde{I}) \vdash \bot$. By the equivalence $I \equiv \top$, we then have $(I \twoheadrightarrow \widetilde{I}) \vdash \bot$. Since $\widetilde{I} \vdash (I \twoheadrightarrow \widetilde{I})$ is easily derivable, we have $\widetilde{I} \vdash \bot$ provable by transitivity as required.

We observe that, as a consequence, $\sim A \equiv A \rightarrow \bot \equiv \neg A$. \Box

Since (Minimal) BBI-provability implies CBI-provability, to establish undecidability for CBI, it suffices (see Figure 1) to prove the analogue of Theorem 9.5 for a CBI-model.

Definition 11.7. We introduce the *RAM-codomain model* $(\mathcal{D}^+, \circ, e_0, \cdot^{-1})$, where \mathcal{D}^+ is the class of finite and co-finite subsets of \mathbb{N} , \circ is the union of disjoint sets (and undefined for nondisjoint sets), the unit e_0 is \emptyset and \cdot^{-1} is set complement.

By extending the valuation ρ_0 in Definition 9.1, we define a valuation ρ_C for $(\mathcal{D}^+, \circ, e_0, \cdot^{-1})$ as follows: ρ_C coincides with ρ_0 on all atomic propositions except *b*, and

$$\rho_C(b) = \rho_0(b) \cup \{ d \in \mathcal{D}^+ \mid d \text{ is co-finite} \}.$$

LEMMA 11.8. $e_0 \models_{\rho_C} \kappa(M)$ for any machine M.

PROOF. As in Lemma 9.3, we must show $e_0 \models_{\rho_C} \kappa(\gamma)$ for any instruction γ . Here we only examine the case of an increment instruction $\gamma = (L_i: c_k + +; \textbf{goto } L_j;)$ for k = 1. We note that we have, as in Lemma 9.3,

$$d \models_{\rho_C} \neg A \Leftrightarrow \forall d'. d, d' \text{ disjoint and } d' \models_{\rho_C} A \text{ implies } d \circ d' \in \rho_C(b). \tag{35}$$

We have $\kappa(\gamma) = (-(l_i * p_1) \twoheadrightarrow -l_i)$. To show $e_0 \models_{e_C} \kappa(\gamma)$, we must show for any $d \in \mathcal{D}^+$.

We have $\kappa(\gamma) = (-(l_j * p_1) - -l_i)$. To show $e_0 \models_{\rho_c} \kappa(\gamma)$, we must show for any $d \in \mathcal{D}^+$, as in the corresponding case of Lemma 9.3,

$$d \models_{\rho_C} -(l_j * p_1) \text{ implies } d \models_{\rho_C} -l_i.$$

Assuming that $d \models_{\rho_c} -(l_j * p_1)$, there are two cases to consider.

First, if d is finite then we can find (as in the corresponding case of Lemma 9.3) $d_j \in \rho_C(l_j)$ and $d_1 \in \rho_C(p_1)$ such that d, d_j and d_1 are disjoint, and thus in particular $d_j \circ d_1 \models_{\rho_C} l_j * p_1$. Using equivalence (35), we have:

$$d \circ d_j \circ d_1 \in \rho_C(b)$$

= $\rho_0(b) \cup \{d \in \mathcal{D}^+ \mid d \text{ is co-finite}\}.$

Since d, d_j , and d_1 are finite, we must have $d \circ d_j \circ d_1 \in \rho_0(b)$ and thus, by the same argument as in the corresponding case of Lemma 9.3, $d \in [\![p_1^{n_1} * p_2^{n_2}]\!]_{\rho_0}$ where $\langle L_j, n_1 + 1, n_2 \rangle \Downarrow_M$ and thus $\langle L_i, n_1, n_2 \rangle \Downarrow_M$ by applying the instruction γ . Consequently, $d \circ d' \in \rho_0(b) \subseteq \rho_C(b)$ for any d' such that d, d' are disjoint and $d' \in \rho_C(l_i)$. Thus, by (35), we have $d \models_{\rho_C} -l_i$ as required.

If, on the other hand, d is co-finite then, for any choice of $d' \in \rho_C(l_i)$ with d, d' disjoint, $d \circ d'$ must also be co-finite, in which case $d \circ d' \in \rho_C(b)$ because $\rho_C(b)$ contains *all* co-finite sets. Thus, again by (35), we have $d \models_{\rho_C} -l_i$ as required.

The other cases follow from their analogues in Lemma 9.3 in a similar fashion. \Box

J. Brotherston and M. Kanovich

LEMMA 11.9. $e_0 \models_{\rho_C} I \land -l_0$ for any machine M.

PROOF. Similar to Lemma 9.4.

THEOREM 11.10. If the sequent $\kappa(M) * l_i * p_1^{n_1} * p_2^{n_2} * (I \wedge -l_0) \vdash b \text{ is valid in the model}$ $(\mathcal{D}^+, \circ, e_0, \cdot^{-1})$, then $\langle L_i, n_1, n_2 \rangle \Downarrow_M$.

PROOF. By the definition of validity, and using Lemma 3.8, we have:

$$\llbracket \kappa(M) * l_i * p_1^{n_1} * p_2^{n_2} * (I \wedge -l_0) \rrbracket_{\rho_C} \subseteq \rho_C(b)$$

that is, $\llbracket \kappa(M) \rrbracket_{\rho_C} \cdot \llbracket l_i * p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_C} \cdot \llbracket I \wedge -l_0 \rrbracket_{\rho_C} \subseteq \rho_C(b).$

By Lemmas 11.8 and 11.9, we have in particular:

$$\llbracket l_i * p_1^{n_1} * p_2^{n_2} \rrbracket_{\rho_C} \subseteq \rho_C(b).$$

Since ρ_C coincides with ρ_0 on all atomic propositions except b, we have $[\![l_i * p_1^{n_1} * p_2^{n_2}]\!]_{\rho_C} = [\![l_i * p_1^{n_1} * p_2^{n_2}]\!]_{\rho_0}$, so that $\langle L_i, n_1, n_2 \rangle$ is uniquely determined according to Lemma 9.2. In particular, $[\![l_i * p_1^{n_1} * p_2^{n_2}]\!]_{\rho_C}$ is finite, so our construction of $\rho_C(b)$ yields $\langle L_i, n_1, n_2 \rangle \downarrow_M$. \Box

Again, based on Figure 1, we can assert the following:

COROLLARY 11.11. The following properties of formulas are undecidable, even when restricted to the language $(\land, \rightarrow, I, *, -*)$ of Minimal BBI⁴:

- (a) provability in CBI;
- (*b*) *provability in* CBI+eW;
- (c) validity in the class of all CBI-models;
- (d) validity in the class of all CBI-models with indivisible units;
- (e) validity in the RAM-codomain model $(\mathcal{D}^+, \circ, e_0, \cdot^{-1})$.

PROOF. Similar to Corollary 5.1. \Box

COROLLARY 11.12. Neither CBI nor CBI+eW has the finite model property.

PROOF. Similar to Corollary 5.2. \Box

12. CONCLUDING REMARKS

Our main contribution in this article is that heap-like memory models, of the type considered in Section 2, have a very complicated logical structure even at the propositional level.

- (A) Separation logic, which provides us with an effective language for reasoning about such memory models, is undecidable even at the purely propositional level.
- (B) Moreover, we have established that for any particular heap-like memory model drawn from the literature, validity in that model is undecidable even for purely propositional formulas in this language. Corollary 5.1(h) provides an infinite number of concrete undecidable models of practical and theoretical importance. That is, however we choose *L*, *RV*, *S* and *P* in Section 2 (with *L* infinite and *RV*, *S*, *P* possibly degenerate), we *always* get an undecidable model.
- (C) We also have established the undecidability of validity in various classes of separation models, and of provability in BBI and CBI and their siblings.

Journal of the ACM, Vol. 61, No. 2, Article 14, Publication date: April 2014.

⁴On the surface, it seems that we are within the framework of Corollary 5.1, since formulas are restricted to the language $(\land, \rightarrow, I, *, \twoheadrightarrow)$, which does not include the new CBI constant I. However, the problem remains nontrivial because of the fact that CBI is not a conservative extension of BBI.

- (D) In fact, to obtain a new exhibit for the "Undecidability Zoo" that is, a minimal version of BBI that is "as simple as possible" we only need to add classical conjunction and implication to the multiplicatives, without invoking either classical negation or falsum (see Section 6).
- (E) From a technical point of view, we kill all our "undecidable birds" with one "stone": a single direct encoding of Minsky machines. This single encoding suffices to cover all cases of interest (see Figure 1).

12.1. New Principles for Separation Logic

In proving our main undecidability results on separation logic, we have found a number of new principles which should be taken into account at the level of the multiplicative unit I.

(i) Though *-contraction, $A \vdash A * A$, is not generally valid in separation logic, in Lemma 6.4, we deduce the following restricted *-contraction

$$\mathbf{I} \wedge \mathbf{A} \vdash \mathbf{A} \ast \mathbf{A}. \tag{36}$$

(ii) As for the systems BBI+eW and CBI+eW newly established in this article, we remark that the memory models of theoretical/practical importance employed in the literature (cf. Section 2) all have indivisible units in the sense of Definition 3.4, which is exactly axiomatized by the *restricted* *-weakening principle of BBI+eW and CBI+eW (see Theorem 3.10):

$$\mathbf{I} \wedge (A \ast B) \vdash A. \tag{37}$$

This principle is in accordance with the following law on "conservation of matter":

"The empty memory cannot be split into nonempty pieces."

12.2. Separation Logic vs. Linear Logic

Our undecidability results also shed new light on the correlations between separation logic and linear logic.

From the point of view of logical principles, there are clear differences between the two. For example, distributivity of additive conjunction over disjunction:

$$A \land (B \lor C) \equiv (A \land B) \lor (A \land C)$$

holds even in BI but fails in linear logic.

More specific to Boolean BI, the restricted *-contraction:

$$I \land A \vdash A * A$$

holds even in Minimal BBI as shown by our Lemma 6.4, but this too fails in linear logic.

Finally, while adding the unrestricted *-weakening $(A * B) \vdash A$ to linear logic gives us a rich structure of *affine logic*, adding it to BBI forces a collapse into classical logic (Proposition 4.7).

From a semantic perspective, the precise expression of properties of memory in separation logic is based on the fact that we have:

$$\llbracket A * B \rrbracket_{\rho} = \llbracket A \rrbracket_{\rho} \cdot \llbracket B \rrbracket_{\rho},$$

that is, the interpretation of A * B is *exactly* the product of the interpretations of A and B. (This fact is also of crucial importance to its undecidability.) Linear logic interpretations deal only with sets that are *closed* with respect to a certain closure operator Cl, which, in particular, violates this exact equality. Indeed, the same is true of BI interpretations [O'Hearn and Pym 1999]. Not only is this less precise, it admits

14:42

no possibility of finite valuations in these logics since, for example, in linear logic even $Cl(\emptyset)$ is always infinite. \Box

12.3. Undecidability vs. Decidable Fragments of Memory Models

Finally, our undecidability results for *concrete* heap-like models give new insights into the nature of decidable fragments of memory models such as those given in Berdine et al. [2004] and Calcagno et al. [2001], as well as imposing boundaries on decidability. For example, we can deduce that to obtain decidability in a heap-like model, one should either give up arbitrary infinite valuations (as in Calcagno et al. [2001]) or restrict the formula language (as in Berdine et al. [2004]). \Box

ACKNOWLEDGMENTS

We are greatly indebted to Peter O'Hearn and Hongseok Yang for their fruitful discussions and suggestions. Thanks to Sam Staton for his observation on effect algebras [Foulis and Bennett 1994], and to Tadeusz Litak who has attracted our attention to Kurucz et al. [1995]. We owe special thanks to the referees for their scrupulous and insightful comments, which have allowed us to significantly improve the exposition.
