

## Speeding Up Ray Tracing

©Anthony Steed 1999, Celine Loscos 2005,  
Jan Kautz 2007-2009

---

---

---

---

---

---

---

---

## Optimisations

- Limit the number of rays
- Make the ray test faster
  - for shadow rays
    - the main drain on resources if there are several lights
  - for primary rays
  - for all rays

Over 90% of the cost of ray tracing is in ray-object intersection tests

---

---

---

---

---

---

---

---

## Ray Tracing Acceleration

- Intersect ray with all objects
  - Way too expensive
- Faster intersection algorithms
  - Little effect
- Less intersection computations
  - Space partitioning (often hierarchical)
    - Grid, octree, BSP or kd-tree, bounding volume hierarchy (BVH)

---

---

---

---

---

---

---

---

### Optimisation for Shadow Rays

- Problem with shadow rays is that for every intersection we trace an additional N rays for each light

---

---

---

---

---

---

---

---

### Optimisation for Shadow Rays: Light Buffer

- Enclose light in a box.
- Cells of box faces store objects

---

---

---

---

---

---

---

---

### Construction (2D Analogue)

C1 - <NULL>      C2 - A, B, C  
 C3 - A            C4 - <NULL>

---

---

---

---

---

---

---

---

### Using the Light Buffer

- Check intersection of ray with polygons stored in cell
- Case with object itself...

---

---

---

---

---

---

---

---

### Optimisation for Primary Rays

---

---

---

---

---

---

---

---

### Optimisation for Primary Rays

- Use a z-buffer!
- Instead of writing colour write an object identifier
  - Easy to support in OpenGL - turn off lighting, do flat shading and encode object id within 24bit colour
- Difficult technique to use elsewhere because rays are no longer spatially coherent and evenly spaced

---

---

---

---

---

---

---

---

### Optimisation for Primary Rays

---

---

---

---

---

---

---

---

### Optimisation for General Rays

- Techniques to use
  - bounding volumes
  - hierarchical bounding volumes
  - space subdivision
    - regular
    - adaptive
  - ray coherence

---

---

---

---

---

---

---

---

### Bounding Volume

- Find a tight bounding volume and use it for a first reject test
- If hit volume then test full object

---

---

---

---

---

---

---

---

### Fast BV Tests (AABB)

- Box-Ray test (when box planes parallel to axes)
  - a box is three sets of parallel planes, each set orthogonal to the other two,
  - ray defined by  $q(t) = q_0 + t \cdot dq$ 
    - Calculate  $t_{near}$  for each of the three plane pairs
    - find max of the 3  $t_{near}$
    - Calculate  $t_{far}$  for each of the three plane pairs
    - find min of the 3  $t_{far}$
  - If  $\max t_{near}$  is greater than  $\min t_{far}$ , then the box is not intersected

---

---

---

---

---

---

---

---

### Fast BV Tests (AABB, 2D case)

---

---

---

---

---

---

---

---

### Choosing a Volume

- Choice depends on the cost of the test and the fit of the shape
  - The "void" area can be very large
- More efficient fitting shapes are possible (this is still a research area e.g. k-dops)

---

---

---

---

---

---

---

---

### Bounding Volume Hierarchy

- Organise a hierarchy of bounding volumes
  - Bounding volumes of bounding volumes

---

---

---

---

---

---

---

---

### Bounding Volume Hierarchy

- Organise a hierarchy of bounding volumes
  - Bounding volumes of bounding volumes

---

---

---

---

---

---

---

---

### Choosing a BVH

- Scene graph might not map to a decent space partitioning
  - Group BVs based on actual proximity rather than scene graph position
- You could e.g., sort the BVH using a BSP tree ...

---

---

---

---

---

---

---

---

### Bounding Volume Hierarchy

- Advantages:
  - Very good adaptivity
  - Efficient traversal  $O(\log N)$
- Problems
  - How to arrange BVs?

---

---

---

---

---

---

---

---

### Regular Spatial Subdivision (Grid)

- Regular 3D grid of "voxels"
- In each voxel, store the list of objects that intersects with the voxel

---

---

---

---

---

---

---

---

### Regular Spatial Subdivision

- Ray traverses the regular grid
- For each traversed voxel, intersection test with stored objects

---

---

---

---

---

---

---

---

**RSS: Issues**

- Grid traversal
  - Requires enumeration of voxel along ray → 3D-DDA
  - Simple and hardware-friendly
  
- Grid resolution
  - Strongly scene dependent
  - Cannot adapt to local density of objects
    - Problem: „Teapot in a stadium“
  - Possible solution: hierarchical grids

---

---

---

---

---

---

---

---

**RSS: Issues**

- Objects in multiple voxels
  - Store only references
  - Use mailboxing to avoid multiple intersection computations
    - Store (ray, object)-tuple in small cache (e.g. with hashing)
    - Do not intersect if found in cache
  - Original mailbox uses ray-id stored with each triangle
    - Simple, but likely to destroy CPU caches

---

---

---

---

---

---

---

---

**Adaptive Spatial Subdivision**

- The octree idea (illustrated with a quadtree!)

---

---

---

---

---

---

---

---

### Quadtree Definition

---

---

---

---

---

---

---

---

### Building a Quadtree

- Split recursively each quad into 4

---

---

---

---

---

---

---

---

### Building the Octree: 3D representation

- Recursively split the cells into eight, until each cell meets some criteria
  - e.g. "only one object intersects each cell"

---

---

---

---

---

---

---

---

### Octree Representation

- Advantage is clear - cells are not wasted on void areas
- Disadvantage:
  - Doesn't build on object shape
    - Object can belong to different branches of the tree
    - Split to isolate the object can be too fine
  - Cost to traverse can be high

---

---

---

---

---

---

---

---

### Octree Drawbacks: Example

---

---

---

---

---

---

---

---

### Tracing an Octree

- Find octree voxel containing start point ( $q_0$ ) or find intersection ( $I$ ) of ray with cube that surround the octree
- **R**: Find ( $I$ ) in the octree
  - it is moved a little along the ray to fall inside a cube
- Intersect ray with faces of the cube it is in,
- Find the intersecting point when the ray exit the voxel
- Repeat at **R** until ray out of the whole volume

---

---

---

---

---

---

---

---

### KD-Tree

- Similar to octree, but **orthogonal** splitting planes are chosen to provide a good search tree

Split based on balancing object numbers and minimising volume disparity

---

---

---

---

---

---

---

---

### BSP Tree

- Generalisation of the kd-tree (which is a generalisation of an octree)
- Choosing your BSP tree is hard!
- Can be done by finding a plane that separates the objects in two equal sets, and applying the subdivision recursively

---

---

---

---

---

---

---

---

### Traversing a BSP tree

- BSP-RayIntersect(Ray, Node)
  - Test if ray interval empty or no more node
  - If node is a leaf, intersect ray with objects
  - Else
    - Clip ray to near side of the plane (RayNear)
    - BSP-RayIntersect(RayNear, Node->near)
    - If (no intersection)
      - Clip ray to far side of the plane (RayFar)
      - BSPIntersect (RayFar, Node->far)

---

---

---

---

---

---

---

---

### Conclusion

- Several can be applied for accelerating the ray intersection tests with the scene
- Some are specific to rays from light source or viewpoints
- Some are more general
- Choosing a good scene partitioning is crucial, but depends on the scene structure
- Need a good trade off between scene partitioning and traversal efficiency (and memory cost)

---

---

---

---

---

---

---
