Abstract

Genetic programming (GP) has proven to be successful at generating programs which solve a wide variety of problems. Object-oriented GP (OOGP) extends traditional GP by allowing the simultaneous evolution of multiple program trees, and thus multiple functions. OOGP has been shown to be capable of evolving more complex structures than traditional GP. However, OOGP does not facilitate the incorporation of expert knowledge within the resulting evolved type. This paper proposes an alternative OOGP methodology which does incorporate expert knowledge by the use of a user-supplied, partially-implemented type definition, i.e., an abstract class.

Background

Types of Genetic Programming

- Tree Based Genetic Programming (Koza-Style)
  - Produces Single S-Expression Trees
  - Facilitates a functional-style program
  - Difficult to represent a state-memory
- Linear Genetic Programming
  - Captures the imperative programming paradigm
  - Uses an array-based chromosome structure
  - Difficult to model multiple behaviours
- Object-Oriented Genetic Programming
  - Multi-tree representation
  - Each tree represents a behaviour

Objective

This work proposes a novel GP paradigm which combines the imperative style of linear GP with the object-oriented approach of OOGP while allowing the incorporation of expert knowledge in the resulting programs. The proposed GP system, LinkableGP, makes use of a partially-implemented type definition, i.e., an abstract class, to allow expert knowledge to be embedded within the evolved program.

Genotype

- The Genotype of an individual consists of a number of chromosomes determined by the number of abstract functions in the Phenotype Abstract Class.
- Each chromosome is an array of integers.
- Crossover consists of 2 phases
  - Mating: where a binary mask determines which chromosomes are inherited by the child
  - Mixing: where one-point crossover operations are performed on randomly selected chromosome pairs

Phenotype

- Each individual is converted from a genotype to its phenotype by mapping each chromosome to an abstract function.
- Each function is built using a set of functions and terminals, called the language.
- Terminals consist of constants, input parameters, and declared variables during the mapping of the abstract function.

Example Phenotype Abstract Class

```java
abstract function initializeGraph()
abstract function selectVertices(graph g, int n)
abstract function createEdge(graph g, vertex v, vertex s)
```

```java
function GeneralizedGraphModel(int n) {
    Result: A graph
    g ← initializeGraph();
    for i ∈ 1..n do
        v ← g.AddVertex(i, n← selectNumber());
        S ← selectVertices(g, n);
        for s ∈ S do
            createEdge(g, v, s);
    end
    end
    return g;
}
```

Experiments

- Evolving Stacks and Queues
  - Evaluated in remove, and peek functions
  - Evaluated based on ability to mimic behaviours
  - 30 runs performed

Table: Results for Evolving Stack and Queue Data Structures

Conclusion

This work proposed a novel genetic programming (GP) paradigm which facilitates the incorporation of expert knowledge within the evolved program structure. The proposed GP system, LinkableGP, was inspired by both linear GP and object-oriented GP (OOGP) methodologies. However, the LinkableGP system combined the benefits of each approach by allowing the simultaneous evolution of multiple, imperative-styled methods. LinkableGP uses a representation whereby an individual is comprised of multiple chromosomes, each of which directly correspond to a method which is to be evolved. Furthermore, LinkableGP facilitates expert knowledge through partially-implemented types, allowing the user to embed portions of the solution known a priori within the resulting individuals.
