Long-Term Evolution of Genetic Programming Populations

1 Why
More challenging problems may require running evolution for longer. Hence the need to study what happens in long runs. Perhaps we can anticipate and solve problems that may occur.

2 Benchmark: 6 input multiplexor

- Six inputs: Use two (D4 D5) as binary number to connect corresponding data lines (D0-D3) to the output
- Test on all $2^6=64$ possible combinations
- Fitness score $(0/64)$ is number correct

3 Introns, Constant, Effective code

- Subtree like whole tree.
- Output of subtree is via its root node
- **Intron**: subtree which has no effect on overall fitness. I.e. its output does not impact on root node of whole tree.
- **Constant** subtree always has same output, i.e. same output on all 64 test cases.
- Remaining effective code has an impact on root node. Typically it is next root node

4 Example Intron: AND function

5 Example constant: zero

$$(\text{AND D0 (NOR D0 D0)}) = 0$$

6 Long term evolution of 6-mux trees

- Terminal set: D0 D1 D2 D3 D4 D5
- Function set: AND OR NAND NOR
- Fitness cases: All $2^6$ combinations of inputs
- Selection: tournament size 7
- Parameters: Ramped half-half depth 2-6. 100% subtree crossover.
- Stop first tree > 1 million nodes

7 Tree Size

8 Evolution of Effective Code

9 A Limit to Bloat

An Edge to Bloat

Bloat cannot continue forever. Even after thousands of generations fitness selection is needed to sustain tree size. When everyone in the population has same fitness, there is no selection. Tree size wanders apparently at random (Gambler’s ruin).

In a finite population trees may become so large that effective code is never disrupted by crossover.

Number runs = popsize $\times$ coresize / treesize

Runts < 1 suggests
treesize $> popsize \times coresize$

Ten smaller pop=50 runs, estimate coresize 500

Estimate treesize about 25 000

The median of ten runs of the mean tree size over 100 000 generations is 42 507.

10 Summary

Run GP for many thousand of generations. See convergence in that almost all of population has same fitness, but every tree is unique. However every tree is the same near their roots and effective code is conserved across many generations.

11 Next

Next:
- Why quadratic increase in size < gen 350
- Existing theory: differences from crossover only limit
- Formalise random drift
- Which types of GP will converge like this?
